## Executive Summary

The Howard County Department of Public Works Stormwater Management Division initiated the Howard County Biological Monitoring and Assessment Program in the spring of 2001. The County initiated the monitoring program to establish a baseline ecological stream condition for all of the County's watersheds. The program involves monitoring the biological health and physical condition of the County's water resources and is designed on a five year rotating basis such that each of the County's 15 watersheds, or primary sampling units (PSU) will be sampled once every five years.

Round 1 was completed from 2001 to 2003, and Round 2 from 2005-2009 with 10 randomly selected sites sampled in each PSU. The current year sampling (2016) is the final year of Round 3 which began in 2012. To allow for paired site comparisons with both Rounds 1 and 2, 30 sites from Round 1 and 30 sites from Round 2 were randomly selected for repeat sampling in Round 3. The remaining 90 sites in Round 3 are newly selected random sites. More specifically, two sites in each Round 3 watershed were randomly chosen from the 10 Round 1 sites and two sites were randomly chosen from the 10 Round 2 sites; the remaining six sites are new random sites.

The Dorsey Run, Hammond Branch, and Rocky Gorge watersheds were re-sampled to fulfill the 2016 sampling requirements and complete Round 3 of the program. These watersheds were previously sampled and assessed by Tetra Tech, Inc, in 2003 during Round 1 (Pavlik and Stribling, 2005), and again by KCI Technologies Inc., in 2009 during Round 2 (Hill and Crunkleton, 2009). The monitoring in each round involved sampling instream water quality, collection and analysis of the biological community (benthic macroinvertebrates) using Maryland Biological Stream Survey (MBSS) protocols, cross section analysis, particle size distribution, and assessment of the physical habitat using the United States Environmental Protection Agency's (EPA) Rapid Bioassessment Protocols (RBP). The sampling methods used are compatible with those used in the second round (2005-2009) with updates where applicable.

The MBSS benthic metrics, scoring criteria, and individual species tolerance were updated by Maryland Department of Natural Resources (DNR) in 2005 (Southerland et al., 2005). The biological data collected in Round 1 sampling of the Dorsey Run, Hammond Branch, and Rocky Gorge watersheds was analyzed using the old metrics (Stribling et. al 1998), and as such, the results are not directly comparable to the current sampling data. Therefore, all data from the 2003 sampling effort were recalculated using the updated metrics to allow for direct comparison to the current data. For this report any mention of 2003 BIBI scores refer to these recalculated values.

All data collection occurred between March 1<sup>st</sup> and May 1<sup>st</sup> of 2016, as required by the MBSS protocols. Sampling sites were marked in the field using survey flagging at the upstream and downstream limits of the reach. The positions of the site midpoints were collected using a GPS unit accurate to within 1-meter.

Biological and physical habitat assessment results for 2016 in Rocky Gorge, Hammond Branch, and Dorsey Run indicate watersheds that are moderately to severely impaired. Only two out of thirty benthic macroinvertebrate samples received a rating of 'Good' and five received a 'Fair' rating. The remaining sites (77%) were rated as either 'Poor' or 'Very Poor.'

Overall, the average watershed physical habitat conditions were 'Partially Supporting' (Rocky Gorge, Dorsey Run) and 'Non-supporting' (Hammond Branch). The geomorphic assessment reveals a variable system. Using the Rosgen classification system for natural rivers (Rosgen, 1996), many of the channels sampled throughout the watersheds were classified as stable type B or C channels. However, a good portion of channels were classified as unstable, incised F channels with also a few channels classified as G channels. Gravel and sand were the dominant substrate types in the majority of sampling reaches, however, silt/clay and cobble dominate streams were also present.

The average percentage of impervious area in the Rocky Gorge, Hammond Branch, and Dorsey Run subwatersheds is 8.8, 12.5, and 33.2%, respectively. Imperviousness for the areas draining to each sampling site range from 7.5% in Hammond Branch to 38.5% in Dorsey run (see Appendix A for impervious values).

Pearson correlations between the BIBI scores and two parameters (percent imperviousness and specific conductivity) showed highly significant relationships. The percentage of imperviousness to each sampling site indicates a strong negative relationship (correlation coeff.= -0.648,  $p < 0.001$ ) to BIBI scores, suggesting biological condition decreases with increased watershed imperviousness. Specific conductivity and BIBI scores also showed a strong negative correlation (correlation coeff.= -0.596,  $p = 0.001$ ). These results support the notion that overall water quality and biological health are likely being affected by the amount of development, and hence imperviousness, in the watershed. A strong correlation was also observed between impervious percent and specific conductivity (correlation coeff.= 0.982,  $p < 0.0001$ ), suggesting that increased conductivity is due in large part to urban runoff.

Results of the 2016 assessment indicate impaired biological conditions in all three watersheds, and statistically significant decreases in mean BIBI scores were observed in Dorsey Run since Round One. Physical habitat scores also showed some statistically significant changes, however, they do not match the trends observed in the BIBI results. Decreases in RBP scores were not observed where decreases in biological condition occurred, which suggests that changes in water quality and/or quantity may be responsible for the impairments.

# 1 Background and Objectives

The Howard County Biological Monitoring and Assessment Program was initiated in the spring of 2001 by the Howard County Department of Public Works Stormwater Management Division. The program involves monitoring the biological health and physical condition of the County's water resources to detect the status and trends at the stream level, the watershed level and ultimately at the County level.

The County initiated the program to establish a baseline ecological stream condition for all of the County's watersheds. The program is designed on a five year rotating basis such that each of the County's 15 watersheds or primary sampling units (PSU) will be sampled once every five years. In general three PSUs would be sampled each year with 10 sites sampled in each PSU. Table 1 includes the full list of PSUs sampled per year and per round and Figure 1 illustrates the program progress to date.

The first sampling rotation was completed in only three years (2001 to 2003). Requirements of the Patuxent Reservoir Watershed Group were addressed in 2001 with sampling conducted in PSUs 2, 5 and 3. This was in addition to sampling conducted in the Little Patuxent subwatersheds (PSUs 11, 12, and 13) under a Watershed Restoration Action Strategy (WRAS) grant. In 2002, only the Middle Patuxent sites (PSUs 6, 7 and 8) were sampled. Additional WRAS funding in 2003 allowed sampling to be completed in the Patapsco River Tributaries (PSUs 1, 4, and 10) in addition to Rocky Gorge, Hammond Branch, and Dorsey Run, which were sampled to supplement the data collected in 2001 for the Little Patuxent.

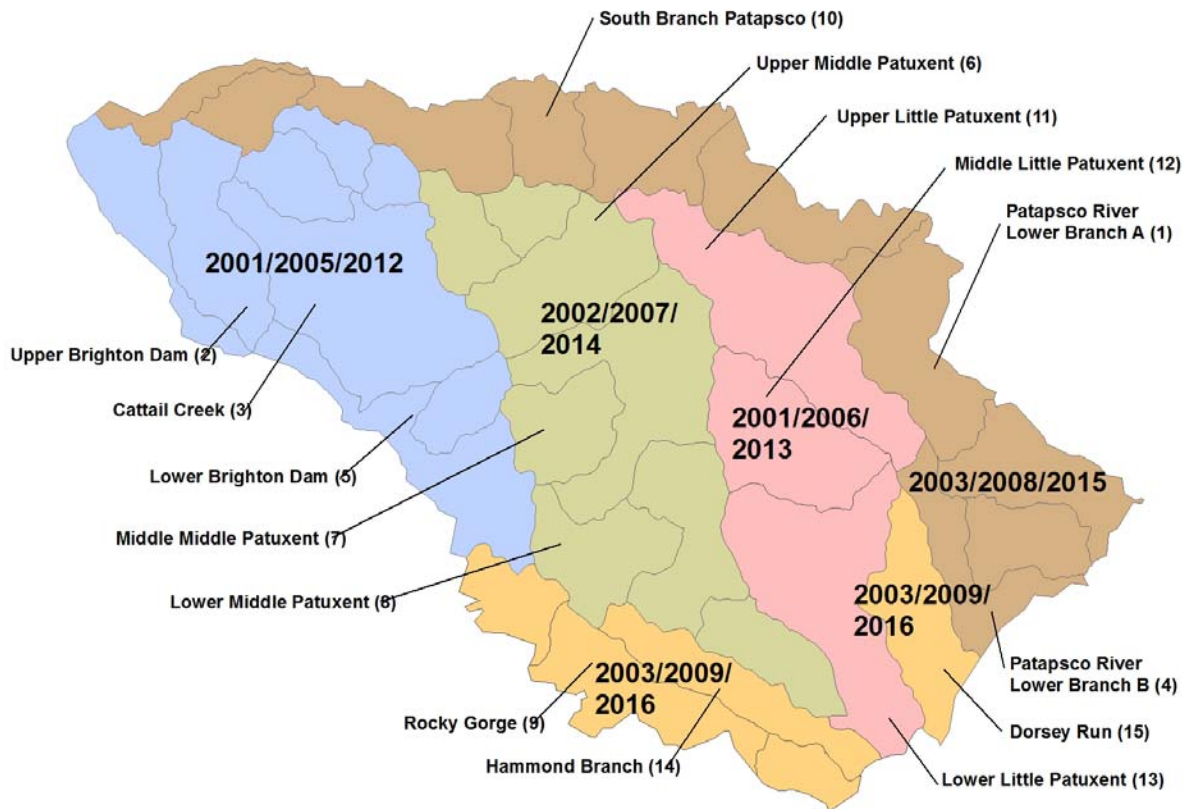

Upper and Lower Brighton Dam (PSUs 2 and 5, respectively) and Cattail Creek (PSU 3) were all sampled as part of the first year of the second round of sampling in 2005. The Little Patuxent River subwatersheds (PSUs 11, 12, and 13) were sampled in 2006 during year two of the second round of sampling. The Middle Patuxent subwatersheds (PSUs 6, 7, and 8) and the Patapsco River subwatersheds (PSUs 1, 4, and 10) were re-sampled in 2007 and 2008, respectively. In 2009, 30 newly selected sites were sampled in the Rocky Gorge Dam (PSU 9), Hammond Branch (PSU 14), and Dorsey Run (PSU 15) subwatersheds to fulfill the 2009 sampling requirements. With the completion of Rocky Gorge Dam, Hammond Branch, and Dorsey Run subwatersheds.

Round 3 (2012 to 2016) of county-wide sampling began with sampling at Upper Brighton Dam (PSU 2), Lower Brighton Dam (PSU 5), and Cattail Creek (PSU 3) during 2012 and with the Little Patuxent River watersheds in 2013 (PSUs 11, 12, and 13). During 2014, Round 3 sampling continued with the sampling of the Middle Patuxent River subwatersheds (PSUs 6, 7, and 8). In 2015, the South Branch Patapsco, Patapsco River Lower Branch A, and Patapsco River Lower Branch B subwatersheds were sampled (PSUs 10, 1, and 4). In 2016, sampling continued in the same order as in Round 2, with Rocky Gorge Dam, Hammond Branch and Dorsey Run. Round 3 sampling includes a combination of repeat site samples and new random site samples to improve trend detection.

Assessment methods follow those developed by Maryland Department of Natural Resources' (DNR) Maryland Biological Stream Survey (MBSS) and the Standard Operating Procedures (SOPs) found in the Quality Assurance Project Plan (QAPP) for the Howard County Biological Monitoring and Assessment Program (Howard County, 2001). The sampling methods used in 2016 are compatible with those used in Round 1 and Round 2, with updates where applicable.

**Table 1 – Summary of Bioassessment Progress**

**Figure 1 - Howard County Bioassessment**

All three subwatersheds sampled in 2016 are located in the southeastern portion of the county and are crossed by several major transportation routes (Figure 2). Interstate I-95 bisects all three watersheds, and State Highway 216 (Scaggsville Road) runs roughly along the border between Hammond Branch and Rocky Gorge subwatersheds. Other major roadways include Clarksville Pike (Route 108), Washington Boulevard (Route 1), Little Patuxent Parkway (Route 175), and Waterloo Road (Route 957). The Rocky Gorge subwatershed is located along the Patuxent River just downstream of Brighton Dam and continues just below Rocky Gorge Dam.

The Rocky Gorge, Hammond Branch, and Dorsey Run subwatersheds are generally located in the transition zone (i.e., Fall Zone) between the piedmont and coastal plain regions. MBSS has developed strata for sampling and analysis of Maryland's streams based on broad physiographic regions, which include the coastal plain, piedmont and combined highlands regions. MBSS's physiographic region strata layer showed that all subwatersheds sampled in 2016 fell within the piedmont physiogeographic region (Figure 2).

**Figure 2 - Location Map of Dorsey Run, Hammond Branch and Rocky Gorge Watersheds**

## 2 Methodologies

Stream monitoring was conducted throughout the watershed and involved measuring instream water quality, sampling and assessing the biological community (benthic macroinvertebrates), visually assessing the instream and riparian physical habitat, and performing cross sectional and substrate particle size measurement and analysis. Monitoring was conducted at 10 sites within each of the three PSUs (Rocky Gorge, Hammond Branch, and Dorsey Run). The assessment methods followed the current MBSS protocols (DNR, 2014) and the SOPs described in the County’s QAPP (DPW, 2001). All data collection occurred between March 29 and April 29, 2016, within the Spring Index Period (March 1 to April 30) as required by the MBSS sampling protocols. Monitoring sites were marked in the field using tree tags (when possible) or survey flagging at the upstream and downstream limits of the reach. The position of each site was collected at the midpoint using a GPS unit accurate to within 2 meters. All field data were entered into a laptop directly in the field. Photographs were taken to document conditions at the time of data collection. A summary of the methods used and the results of the monitoring are documented in this report.

## 2.1 Selection of Sampling Sites

The sampling design employed both a repeat and randomized census approach stratified by stream order, with a total of 30 sites distributed among the three PSUs. Ten sites were located in each subwatershed.

To select primary and alternate sampling sites, stream lengths were summed by stream order within each subwatershed. The length of stream by stream order and its percentage of the total length within the subwatershed determined the number of sites selected on that order stream.

To allow for direct comparison of results over time and between sampling rounds, two sites from Round One (2003) and two sites from Round Two (2009) were selected for resampling in each PSU. The remaining six sites in each PSU were randomly selected. The randomized approach was then applied within each subwatershed. The National Hydrography Dataset (NHD) stream layer was divided into 1-meter reaches and each reach was assigned a number. A random number generator was used to select sampling reaches for 2015. Both primary and alternate sites were selected in case the primary site was ephemeral (dry), inaccessible, or unsafe to sample. Site codes contain the PSU code and initials of the watershed (09RG), stream order (1), a two-digit sequential number (01), either an “R” or an “F” indicating that the site is a randomly selected site (i.e., R) or a fixed “revisit” site (i.e., F), the year sampled (2016), and a letter used in the field to differentiate sampling sites (e.g., 09RG-102-R-2016A).

Three additional biological samples were collected as quality assurance/quality control (QA/QC) samples at duplicate sites, one in each of the three subwatersheds. Biological sampling, habitat assessments and water quality measurements were repeated at the duplicate sites. These sites were selected in the field. Duplicate sampling reaches were the same length as the paired sampling sites (75 meters), were located immediately upstream of their paired sampling sites, had similar habitat characteristics and were not impacted by road crossings or confluences.

## 2.2 Impervious Surface and Land Use Analysis

An analysis was conducted to derive the impervious surface acreage, percent impervious, and land use make up for each of the site drainage areas to evaluate their effect on biological condition. Drainage areas were first delineated to each sampling site using a combination of ArcGIS Hydro tools and two-foot contours. Land use was derived from Maryland Department of Planning (MDP) 2010 land use for Howard County. Since the Patuxent River is a large watershed draining several counties, additional GIS data from Montgomery County was also used to delineate drainage areas and calculate imperviousness based on land use. Impervious values were derived primarily using Howard County’s 2014 planimetric impervious surface layer which includes detailed polygons of roadways, rooftops, parking lots, sidewalks etc. For portions of the Patuxent River that extend beyond Howard County for which the impervious layer was not available, values for percent impervious by land use were derived from the Natural Resources Conservation Services (NRCS) TR-55 (USDA, 1986). This approach was applied only to the six fourth-order sites in the Rocky Gorge PSU. A table with the percent of land use in each subwatershed and the calculated imperviousness is included in Appendix A.

## 2.3 Water Quality Sampling

To supplement the macroinvertebrate sampling and habitat assessment, instream water quality measurements were performed. Field water quality measurements were collected *in situ* at all sites according to methods in the County QAPP. Each parameter listed in Table 2 was recorded at the upstream portion of each sampling reach (including field QC sites). Most *in situ* parameters were measured using a YSI® Professional Plus series multiprobe water quality meter. Turbidity was

measured with a Hach® 2100 Turbidimeter. Water quality meters were regularly inspected, maintained, and calibrated to ensure proper usage and accuracy of the readings. Calibration logs were kept by field crew leaders and checked by the project manager regularly.

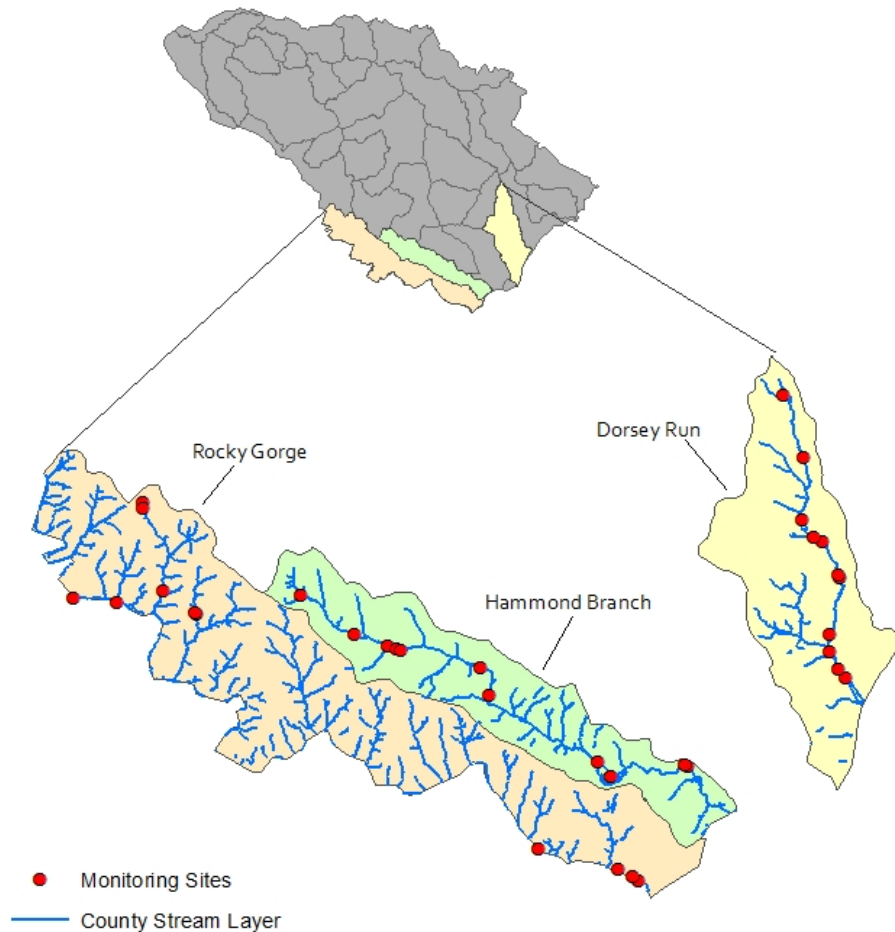

The Maryland Department of the Environment (MDE) has established acceptable standards for several water quality parameters for each designated Stream Use Classification. These standards are listed in the *Code of Maryland Regulations (COMAR) 26.08.02.03-03 - Water Quality* (MDE, 1994). The Rocky Gorge, Hammond Branch, and Dorsey Run drainage areas are in *COMAR* Sub-Basin 02-13-11: Patuxent River Area. The Rocky Gorge subwatershed below Rocky Gorge Dam along with Hammond Branch and Dorsey Run subwatersheds are all classified as Use I-P, Water Contact Recreation, Protection of Aquatic Life, and Public Water Supply. The Patuxent River below Brighton Dam and above Rocky Gorge Dam is classified as a Use IV-P water body, Recreational Trout Waters and Public Water Supply. The acceptable standards for Use I-P and IV-P streams are listed in Table 2. A comparison of these standards to data collected at each station is included in the site summary text in Section 3.1.

**Table 2 - Water Quality Sampling and COMAR Standards, Use I-P and IV-P Waters**

| Parameter             | Units                              | Acceptable COMAR Standard  |
|-----------------------|------------------------------------|--|
| pH                    | standard pH units                  | 6.5 to 8.5   |
| Temperature           | degrees Celsius, °C                | Use I-P: maximum of 90°F (32°C) or ambient temperature of the surface water, whichever is greater    |
|                       |                                    | Use IV-P: maximum of 75°F (23.9°C) or ambient temperature of the surface water, whichever is greater |
| Dissolved Oxygen (DO) | milligrams per liter, mg/L         | may not be less than 5 mg/L at any time  |
| Conductivity          | microSiemens per centimeter, µS/cm | no COMAR standard set  |
| Turbidity             | Nephelometer Turbidity Units, NTU  | maximum of 150 NTUs and maximum monthly average of 50 NTUs   |

## 2.4 Biological Sampling

Biological monitoring was conducted throughout the Rocky Gorge, Hammond Branch, and Dorsey Run watersheds following methods detailed in the County’s QAPP (DPW, 2001). Biological assessment methods within Howard County are designed to be consistent and comparable with the methods used by Maryland Department of Natural Resources (DNR) in their Maryland Biological Stream Survey (MBSS). The County has adopted the MBSS methodology to be consistent with statewide monitoring programs and programs adopted by other Maryland counties. The methods have been developed locally and are calibrated to Maryland’s physiographic regions and stream types. Because MBSS methods dictate that habitat assessments occur during the Summer Index Period while sampling fish communities, which the County does not complete, physical habitat condition was assessed using the EPA’s Rapid Bioassessment Protocol (RBP) (Barbour et. al, 1999) habitat assessment for high-gradient streams. Certain MBSS habitat parameters, namely percent shading, require full leaf out to accurately assess, which is often misrepresented during the Spring Index Period when leaves typically have not yet opened. However, it should be noted that MBSS physical habitat data is collected to supplement RBP data, and potentially for use in future investigations or comparisons. Locations of the bioassessment sites are shown in Figure 3 with the (NHD) stream layer.

**Figure 3 – Dorsey Run, Hammond Branch and Rocky Gorge Bioassessment Sampling Locations**

### ***2.4.1 Benthic Macroinvertebrate Sampling***

Benthic macroinvertebrate collection followed the QAPP which closely mirrors MBSS procedures (DNR, 2014). Benthic macroinvertebrate sampling is conducted during the Spring Index Period (March 1<sup>st</sup> to April 30<sup>th</sup>) along a 75-meter reach. The multi-habitat D-frame net approach was used to sample a range of the most productive habitat types within the reach. In this sampling approach, a total of twenty jabs are distributed among all available habitats within the stream system and combined into one composite sample. Sampled habitats include submerged vegetation, overhanging bank vegetation, leaf packs, mats of organic matter, stream bed substrate, submerged materials (i.e., logs, stumps, snags, dead branches, and other debris) and rocks.

### ***2.4.2 Sample Processing and Laboratory Identification***

Benthic macroinvertebrate samples were processed and subsampled according to methods described in the MBSS *Laboratory Methods for Benthic Macroinvertebrate Processing and Taxonomy* (Boward and Friedman, 2000). Subsampling is conducted to standardize the sample size and reduce variation caused by samples of different sizes. In this method the sample is spread evenly across a gridded tray and each grid is picked clean of organisms until a count of 120 is reached. The 120-organism target is used to allow for specimens that are missing parts or are not a late enough instar for proper identification. If samples were sorted beyond the 120-organism target, the sample was spread in a petri dish subdivided into grids and re-sampled by randomly selecting grids and counting all specimens in each grid until the sample was within an acceptable range.

The samples were sent to a lab (Aquatic Resources Center<sup>1</sup>) for identification. Identification of the samples was conducted to the genus level for most organisms. Groups including Oligochaeta and Nematomorpha were identified to the family level while Nematoda was left at phylum. Individuals of early instars or those that were damaged were identified to the lowest possible level, which in most cases was family. Chironomidae was further subsampled depending on the number of individuals in the sample and the numbers in each subfamily or tribe. Most taxa were identified using a stereoscope. Temporary slide mounts were used to identify Oligochaeta to family with a compound scope. Chironomid sorting to subfamily and tribe was also conducted using temporary slide mounts. Permanent slide mounts were then used for final genus level identification. Results were logged on a bench sheet and entered into a spreadsheet for analysis.

### ***2.4.3 Biological Data Analysis***

Data was analyzed using methods developed by MBSS as outlined in the *New Biological Indicators to Better Assess the Condition of Maryland Streams* (Southerland et al., 2005). The Benthic Index of Biotic Integrity (BIBI) approach involves statistical analysis using metrics that have a predictable response to water quality and/or habitat impairment. The metrics selected fall into five major groups including taxa richness, taxa composition, tolerance to perturbation, trophic (feeding) classification and taxa habit.

Raw values from each metric are given a score of 1, 3 or 5 based on ranges of values developed for each metric. The results are combined into a scaled BIBI score ranging from 1.0 to 5.0, and a corresponding narrative rating is applied. Three sets of metric calculations have been developed for Maryland streams based on broad physiographic regions. These include the coastal plain, piedmont and combined highlands physiogeographic regions. The Rocky Gorge, Hammond Branch, and Dorsey Run subwatersheds are all located in the piedmont physiogeographic region (see Figure 2).

The benthic metrics, scoring criteria, and individual species tolerance were updated by DNR in 2005. The data collected in the first round of sampling of the Rocky Gorge, Hammond Branch, and Dorsey Run subwatersheds was analyzed using the old metrics (Stribling et. al 1998), and as such, the results were not directly comparable to the 2009 and 2016 sampling data. Therefore, all data from the 2003 sampling were recalculated using the updated metrics to allow for direct comparison to the current data (KCI, 2008). For this report, any mention of 2003 BIBI scores refer to these recalculated values.

The following metrics and BIBI scoring were used for data analysis:

#### **Piedmont BIBI Metrics:**

*Number of Ephemeroptera Taxa* – Equals the total number Ephemeroptera Taxa in the sample. Ephemeroptera are generally considered pollution sensitive, thus communities dominated by Ephemeroptera usually indicate lower disturbances in water quality.

---

<sup>1</sup> Address: 545 Cathy Jo Circle, Nashville, TN

*Total Number of Taxa* – Equals the richness of the community in terms of the total number of genera at the genus level or higher. A large variety of genera typically indicate better overall water quality, habitat diversity and/or suitability, and community health.

*Number of EPT Taxa* – Equals the richness of genera within the Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies). EPT taxa are generally considered pollution sensitive, thus higher levels of EPT taxa would be indicative of higher water quality.

*Percent Intolerant Urban* – Equals the percentage of individuals in the sample that are considered intolerant to urbanization (tolerance values [TV] = 0 – 3). The percent of intolerant urban is expected to decrease with decreasing water quality.

*Percent Chironomidae* – Equals the percentage of individuals in the sample that are in the Chironomidae family. An increase in the percentage of Chironomidae is generally an indicator of decreasing water quality.

*Percent Clingers* – Equals the percentage of the total number of individuals who are adapted to attaching to surfaces in stream riffles. Higher percentages of clingers are representative of a decrease in stressors and higher water quality.

Information on trophic or functional feeding group and habit were based heavily on information compiled by DNR and from Merritt and Cummins (1996). Scoring criteria for the piedmont BIBI is shown below in Tables 3. The raw metric value ranges are given with the corresponding score of 1, 3 or 5. Table 4 provides the BIBI scoring ranges and corresponding biological condition ratings.

**Table 3 – Biological Index Scoring for Piedmont Benthic Macroinvertebrates**

| Metric                       | Score |          |     |
|------------------------------|-------|----------|-----|
|                              | 5     | 3        | 1   |
| Total Number of Taxa         | ≥25   | 15 – 24  | <15 |
| Number of EPT Taxa           | ≥11   | 5 – 10   | <5  |
| Number of Ephemeroptera Taxa | ≥4    | 2 – 3    | <2  |
| Percent Intolerant Urban     | ≥51   | 12 – 50  | <12 |
| Percent Chironomidae         | ≤4.6  | 4.7 – 63 | >63 |
| Percent Clingers             | ≥74   | 31 – 73  | <31 |

**Table 4 – BIBI Scoring and Rating**

| BIBI Score | Narrative Rating |
|------------|------------------|
| 4.0 – 5.0  | Good             |
| 3.0 – 3.9  | Fair             |
| 2.0 – 2.9  | Poor             |
| 1.0 – 1.9  | Very Poor        |

## 2.5 Physical Habitat Assessment

Each biological monitoring site is characterized based on physical characteristics and various habitat parameters following the Environmental Protection Agency’s Rapid Bioassessment Protocol (RBP) habitat assessment for high gradient streams (Barbour et. al, 1999). The RBP habitat assessment consists of visually assessing ten biologically significant habitat parameters that evaluate a stream’s ability to support an acceptable level of biological health. Each parameter is given a numerical score from 0-20 and a categorical rating of optimal, suboptimal, marginal or poor. Overall habitat quality typically increases as the total score for each site increases. The parameters assessed for high gradient streams are listed in Table 5.

**Table 5 – RBP Habitat Parameters - High Gradient Streams**

| Parameters Assessed                 |                                |
|-------------------------------------|--------------------------------|
| Epifaunal substrate/available cover | Channel alteration             |
| Embeddedness                        | Frequency of riffles/bends     |
| Velocity/depth regime               | Bank stability                 |
| Sediment deposition                 | Vegetative protection          |
| Channel flow status                 | Riparian vegetative zone width |

The above parameters for each site (including QC sites) were summed to obtain a total habitat score. Since a reference score analysis has not been developed for Howard County watersheds, the percent comparability was calculated based on the highest attainable score (200). The percent of reference score, or percent comparability score, is then used to place each site into corresponding narrative rating categories as shown in Table 6.

**Table 6 – RBP Habitat Score and Ratings**

| Percent of Reference | Narrative Rating        |
|----------------------|-------------------------|
| >90.0                | Comparable to Reference |
| 75.1 – 89.9          | Supporting              |
| 60.1 – 75.0          | Partially Supporting    |
| <60.0                | Non-supporting          |

## 2.6 Geomorphic Analysis

The goal of the physical monitoring was to create a geomorphic characterization of the stream channels in the watershed. Assessment techniques include the cross sectional survey, substrate particle size analysis and measurement of channel slope.

### 2.6.1 Cross Section Analysis

Cross sections were surveyed at each monitoring station to develop a channel characterization and measurement of cross sectional area and discharge. Methods followed the Howard County SOP. Each cross section was located on a representative cross-over reach and was surveyed with a laser level and stadia rod.

The cross sections include survey of the floodplain and all pertinent channel features including:

- Top of bank
- Bankfull elevation
- Edge of water
- Limits of point and instream depositional features
- Thalweg
- Floodprone elevation

Sinuosity was calculated based on the length of the field-surveyed profile and the straight-line distance between the top and bottom of each profile. The floodprone width is estimated at an elevation two times the bankfull depth.

Where possible, additional survey points were taken near the upstream, midpoint, and downstream end of the sampling reach to obtain the slope through the reach so that estimates of discharge could be derived. Survey points for slope calculations were typically taken at the top of riffle features, although this was not always possible, especially for sampling reaches on the Patuxent River mainstem that contained only one riffle in the vicinity of the sampling reach.

The stream cross section, bed and bank material data and profile information (including slope) were analyzed using the Ohio Department of Natural Resources Reference Reach Spreadsheet Version 4.3L (Mecklenburg, 2006). The following values and ratios were calculated:

|                     |                    |                             |
|---------------------|--------------------|-----------------------------|
| Sinuosity           | Entrenchment ratio | Bankfull cross section area |
| Slope               | Bankfull height    | Velocity                    |
| Floodprone width    | Bankfull width     | Discharge                   |
| Width / depth ratio | Mean depth         | Shear stress                |

### ***2.6.2 Particle Size Analysis***

The channel bed and bank materials were characterized at each cross section using pebble count analysis. A single pebble count, modified from the technique developed by Wolman (1954), was conducted in each reach to determine the composition of channel materials and the median particle size for each site. The pebble count procedure was adapted from *Stream Channel Reference Sites: An Illustrated Guide to Field Technique* (Harrelson et al, 1994). The pebble count was conducted at 10 transects across the entire assessment reach. Transects were positioned based on the proportion of riffles/pools/runs in the assessment reach as estimated by visual inspection. The count was conducted within the entire bankfull channel. The pebble counts provide roughness values necessary for calculations of velocity and discharge.

### ***2.6.3 Rosgen Classification***

Additionally, a Rosgen Level II characterization (Rosgen, 1996) was completed for each stream reach based on field-collected data. Table 7 includes general descriptions for each channel type classification based on the Rosgen classification system for natural rivers (Rosgen, 1996).

**Table 7 – Rosgen Level II Channel Type Description**

| Channel Type | General Description (from Rosgen, 1996)   |
|--------------|---|
| Aa+          | Very steep, deeply entrenched, debris transport, torrent streams.   |
| A            | Steep, entrenched, confined, cascading, step/pool streams. High energy/debris transport associated with depositional soils. Very stable if bedrock or boulder dominated channel.  |
| B            | Moderately entrenched, moderate gradient, riffle dominated channel with infrequently spaced pools. Moderate width/depth ratio. Narrow, gently sloping valleys. Very stable plan and profile. Stable banks.                |
| C            | Low gradient, meandering, slightly entrenched, point-bar, riffle/pool, alluvial channels with broad, well-defined floodplains.  |
| D            | Braided channel with longitudinal and transverse bars. Very wide channel with eroding banks. Active lateral adjustment, high bedload and bank erosion.  |
| DA           | Anastomosing (multiple channels) narrow and deep with extensive, well-vegetated floodplains and associated wetlands. Very gentle relief with highly variable sinuosities and width/depth ratios. Very stable streambanks. |
| E            | Low gradient, Highly sinuous, riffle/pool stream with low width/depth ratio and little deposition. Very efficient and stable. High meander/width ratio.   |
| F            | Entrenched, meandering riffle/pool channel on low gradients with high width/depth ratio and high bank erosion rates.  |
| G            | Entrenched “gully” step/pool and low width/depth ratio on moderate gradients. Narrow valleys. Unstable, with grade control problems and high bank erosion rates.  |

### 3 Results

#### 3.1 Subwatershed Summaries

A total of 30 sites were sampled in the Rocky Gorge, Hammond Branch, and Dorsey Run subwatersheds, ten within each individual subwatershed. Additionally, one biological QA/QC sample was collected in each subwatershed at stations where upstream habitat was considered similar. The summary results of the habitat assessment, biological assessment, land use, and Rosgen characterization (Rosgen, 1996) are divided among the three subwatersheds and presented in detail in this section. Maps of each subwatershed displaying the results of the RBP habitat assessment and BIBI are presented in Figures 4, 5 and 6. Summary data for each PSU is included in Tables 8, 9 and 10. Full data results are displayed in Appendices A through F.

##### 3.1.1 Rocky Gorge

In 2016, five of the ten sampling sites in the Rocky Gorge subwatershed were on first order streams and five were on fourth order streams. The field QC sample was collected at site 09RG-102R-2016A-QC. The subwatershed had an average BIBI score of 2.77 and a ‘Poor’ condition rating, with scores ranging from 1.33 to 4.67. The average RBP habitat assessment comparability score is 67, or ‘Partially-Supporting’, with scores ranging from 58.5% (‘Non-supporting’) to 92% (‘Comparable to Reference’). Channels were generally classified as Rosgen type B, C, or F types with predominantly gravel/sand substrate. A summary of the results for the Rocky Gorge subwatershed is found in Table 8.

## Rocky Gorge Site Descriptions:

### 09RG-102-R-2016A

This site is located on an unnamed tributary to Rocky Gorge Reservoir upstream of where it empties into the reservoir. Gravel was the dominant substrate type of this B4c channel. Within the 242-acre drainage area, the predominant land use is very low density residential (25.8%) followed by agriculture (25.9%), institutional (18.2%), and forest (15.4%). Impervious land cover accounted for 8.3% of the drainage area, in line with the subwatershed average of 8.8%. The RBP physical habitat assessment resulted in a score of 63.5, with a rating of 'Partially Supporting'. The banks were observed to be stable with suboptimal benthic substrate. The PHI score was a 68.3 with a rating of 'Partially Degraded.' There were a total of 25 taxa in the benthic macroinvertebrate sample with 12 EPT taxa present. Over half of the sample (68%) consisted of individuals intolerant to urban stressors, with 33 of the 68% being *Dolophilodes* with a (tolerance value [TV] = 1.7). At 18%, this station had one of the lowest percentages of individuals of the Chironomidae family (midges). This station received an overall BIBI score of 4.7 and a 'Good' biological classification. Water quality results indicated all parameters were within acceptable COMAR standards.

### 09RG-104-R-2016B

This site is located on an unnamed F4/5 stream that drains into the Patuxent River above Clarksville Pike. The site is surrounded by forest and low density wooded residential properties. However, water quality results indicated no parameters exceeding acceptable COMAR standards. The 721-acre drainage area had 7.3% impervious land cover. The predominant land use is very low density residential (37.6%) followed by low density residential (27.9%) and forest (15.4%). RBP habitat was rated as 'Partially Supporting' and received a comparability score of 63.0 due to suboptimal habitat and moderately stable bank stability. The reach received a PHI score of 72.9, rating it as 'Partially Degraded.' Gravel and sand were the dominant substrate types for this sampling reach. The station received an overall BIBI score of 4.00 and a 'Good' classification. This is a result of the benthic macroinvertebrate sample consisting of a high total number of taxa (25 taxa) with eight EPT taxa present and a high percentage of individuals intolerant to urban stressors (51%).

### 09RG-119-F-2016G

This sampling reach is located on a small, B6 stream that drains a private pond and is located on farm land. The site was predominately silt/clay substrate. At 47 acres, this site has the smallest drainage area of the Rocky Gorge sites. Low density residential land use accounts for 48.5%, followed by very low density residential (40.7%) and forest land cover at 10.7%. The high percentage of low density residential land use results in a drainage area with 10.0% imperviousness, which is above the subwatershed average of 8.8%. The source of flow from this stream is a private pond and the sampling location was between two small farm properties. Water quality indicated elevated pH levels of 9.49 which is above the maximum COMAR standard of 8.5. Further investigation would need to be done to find the cause, but sampling occurred at the beginning of the growing season during a period when potential lime application to fields could cause a rise in pH. The RBP habitat assessment indicated a 'Non-supporting' habitat with a comparability score of 58.5 due to poor scores for epifaunal substrate/available cover, velocity/depth regime, frequency of riffles, and riparian zone width on the right bank. The PHI score was 37.4, the lowest in the subwatershed, and a narrative rating of 'Severely Degraded.' This station received the second lowest BIBI score of 1.67 with a narrative rating of 'Very Poor'. There were a total of 17 taxa present in this benthic macroinvertebrate sample and no EPT taxa. This station also had only 13% individuals intolerant to urban stressors, while having 83% Chironomids (midges).

#### **09RG-124-F-2016I**

This site is located on a small, F4b headwater stream downstream of site 09RG-119-F-2016G with a substrate consisting of mostly gravel and sand. This site is located next to a private pond and has a small pipe draining into the reach. This site drains an area of 77 acres. Very low density residential land use accounts for 42.1%, followed by low density residential at 41.5% and forest land cover at 16.4%. Impervious land cover for this subwatershed, is 8.9%, in line with the subwatershed average of 8.8%. This site received an RBP habitat score of 59.5 with a rating of 'Non-supporting'. The PHI score was a 58.1 with a rating of 'Degraded.' Water quality results indicated all parameters within acceptable COMAR standards. There were 31 taxa present in this benthic macroinvertebrate sample, with nine EPT taxa. Forty-three percent of the individuals were intolerant to urban stressors. As a result, this site received a BIBI score of 3.33 with a narrative rating of 'Fair.'

#### **09RG-407-R-2016C**

This site is located on a fourth-order primarily run segment of the Patuxent River, downstream of Route 216. This stream was classified as a B4/5c channel with predominately sand and gravel substrate. Impervious land cover accounted for 9.5% of the 87,675-acre drainage area, slightly above the subwatershed average. The predominant land use for this site is agriculture (30.8%) followed by forest land cover (30.0%) and low density residential (17.1%). Suboptimal habitat, optimal velocity/depth regime and channel flow status resulted in a RBP habitat score of 67.5 and a rating of 'Partially Supporting'. The PHI was scored at 68.1 with a narrative rating of 'Partially Degraded.' The benthic macroinvertebrate sample for this site was the lowest of all Rocky Gorge sites with 19 taxa, four of which were EPT taxa, and only one Ephemeroptera taxon present. Chironomids (midges) accounted for 74% of the sample, while only four percent consisted of individuals intolerant to urban stressors. Based on the BIBI score of 1.33, this site was given a 'Very Poor' biological condition rating. Water quality results indicated all parameters within acceptable COMAR standards.

#### **09RG-410-R-2016D**

This sampling reach is located on the Patuxent River mainstem downstream of I-95 and is classified as a B3c channel, with a substrate predominately consisting of cobble and gravel. At 86,280 acres, this site had the second largest drainage area for the entire Rocky Gorge subwatershed with 9.1% of the drainage area consisting of impervious land cover. Land use in the drainage area is primarily agriculture and forested land cover (31.3% and 30.1%, respectively) followed by low density residential (17.2%). This site scored the highest PHI in the watershed at 84.9 and a rating of 'Minimally Degraded.' For RBP habitat, this site scored the highest in the Rocky Gorge watershed. With optimal scores in every category, this reach received a habitat score of 92.0 with a 'Comparable to Reference' classification. 'Comparable to Reference' means that it received scores similar to the best quality streams possible. The water quality results indicated no parameters that exceeded acceptable COMAR standards. Due to the depth of the sampling reach, benthic macroinvertebrate sampling was performed entirely along one bank of the reach. There were a total of 17 taxa in the benthic macroinvertebrate sample, four of which were EPT taxa, with two Ephemeroptera taxa present. Close to half of this sample (42%) was comprised of Chironomids (midges). Only two percent of the sample consisted of individuals intolerant to urban stressors and no climbers were present in the sample. Although the habitat received very high scores, the low level of intolerant individuals and complete lack of climbers contributed to an overall BIBI score of 2.00 for this site, resulting in a 'Poor' biological condition rating.

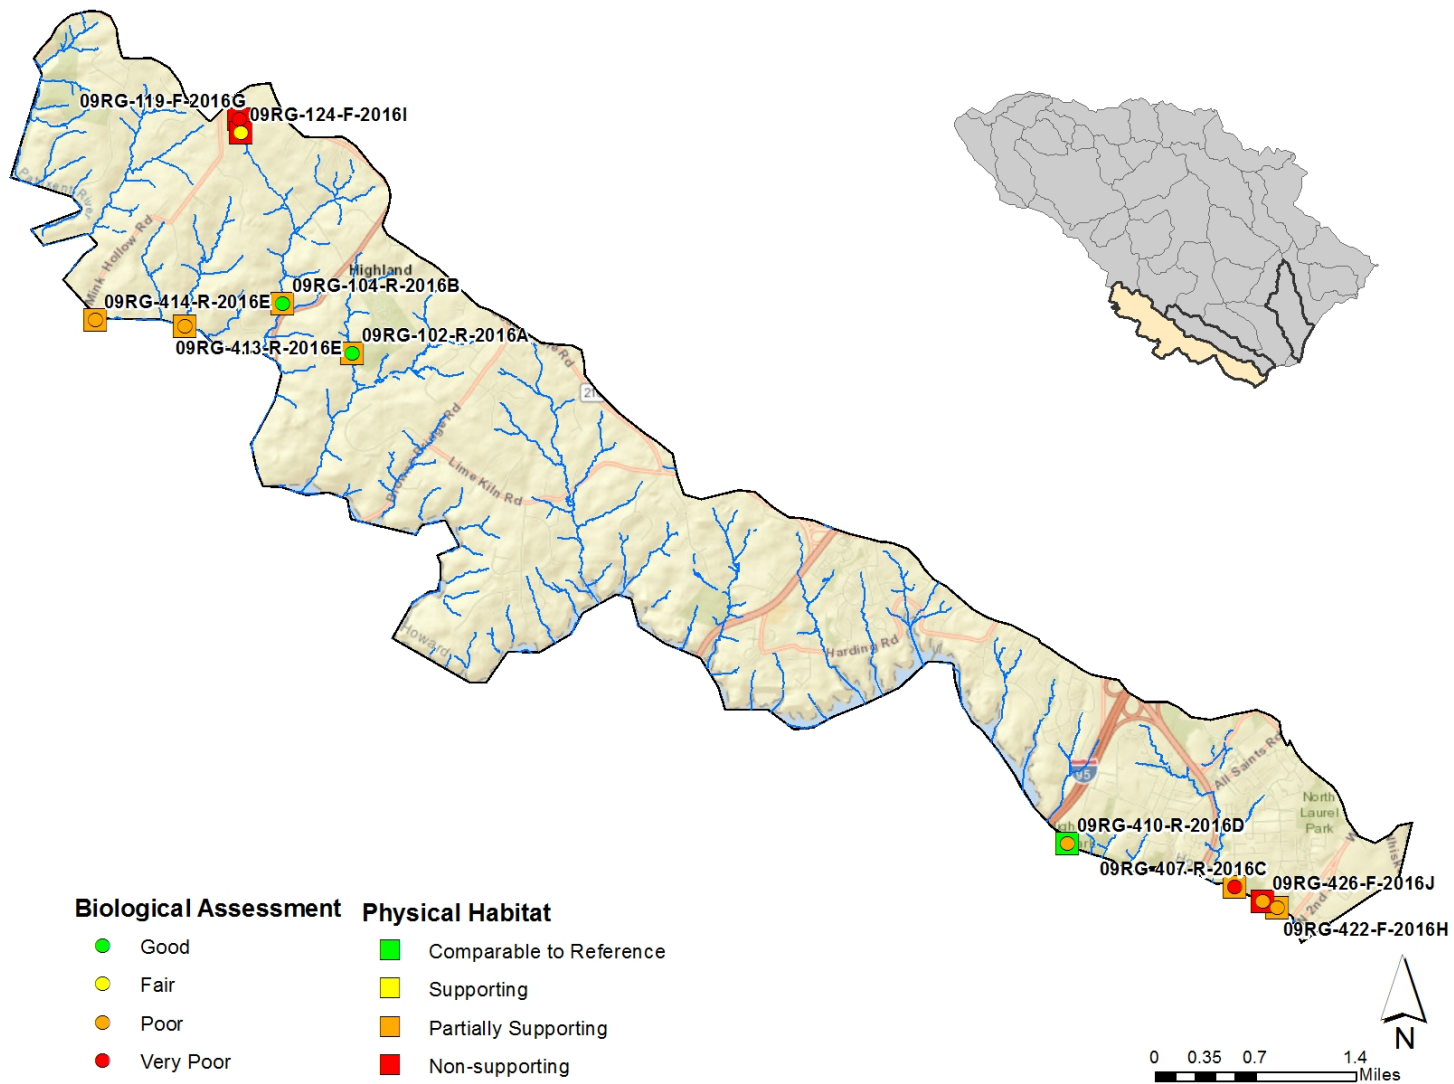

Figure 4 – Rocky Gorge PSU Sampling Results

**Table 8 - Rocky Gorge Summary**

| Site ID            | Drainage Area (ac) | Impervious Surface Percent | BIBI Score | BIBI Rating | RBP Comparability Score | RBP Rating              | PHI Score | PHI Rating         | Rosgen Channel Type |
|--------------------|--------------------|----------------------------|------------|-------------|-------------------------|-------------------------|-----------|--------------------|---------------------|
| 09RG-102-R-2016A*  | 243                | 8.3                        | 4.67       | Good        | 58.5                    | Non-supporting          | 68.3      | Partially Degraded | B4c                 |
| 09RG-104-R-2016B   | 721                | 7.3                        | 3.67       | Fair        | 67.5                    | Partially Supporting    | 72.9      | Partially Degraded | F4/5                |
| 09RG-119-F-2016G   | 47                 | 10.0                       | 4.00       | Good        | 92.0                    | Comparable to Reference | 37.4      | Severely Degraded  | B6                  |
| 09RG-124-F-2016I   | 77                 | 8.9                        | 1.67       | Very Poor   | 74.0                    | Partially Supporting    | 58.1      | Degraded           | F4b                 |
| 09RG-407-R-2016C   | 87,675             | 9.5                        | 3.33       | Fair        | 60.5                    | Partially Supporting    | 68.1      | Partially Degraded | B4/5c               |
| 09RG-410-R-2016D   | 86,280             | 9.1                        | 1.33       | Very Poor   | 59.0                    | Non-supporting          | 84.9      | Minimally Degraded | B3c                 |
| 09RG-413-R-2016E   | 71,112             | 8.1                        | 2.00       | Poor        | 63.5                    | Partially Supporting    | 75.8      | Partially Degraded | C4/5                |

\*QC sampling was conducted at this site

**09RG-413-R-2016E**

This site, located on the Patuxent River mainstem above Clarksville Pike was classified as a C4/5 channel with predominately sand substrate. At 71,112 acres, 8.1% of which was impervious land cover, this drainage area consisted primarily of agriculture (35.4%) and forested land cover (29.3%) followed by low density residential (16.1%). This site received a PHI score of 75.8 and a rating of 'Partially Degraded.' Suboptimal to optimal scores for RBP habitat were given for most parameters, with the exception of a marginal rating for sediment deposition, resulted in a score of 74.0 and a rating of 'Partially Supporting.' Water quality results indicated all parameters within acceptable COMAR standards. This station received a BIBI rating of 'Poor' with a score of 2.67. Seventeen total taxa were present in this benthic macroinvertebrate sample, five of which were EPT taxa and two of which were Ephemeroptera taxa. Only six percent of the sample consisted of individuals intolerant to urban stressors. The benthic sample consisted of 60% clingers and 28% tolerant midges

**09RG-414-R-2016E**

This sampling reach is located in a large, deep pool feature of the Patuxent River just downstream of Mink Hollow Road. The predominant land use is agriculture (35.6%), followed by forested land cover (29.2%) and low density residential (16.1%). Of the 70,729-acre drainage area, 8.1% was comprised of impervious land cover. This site received a PHI score of 74.2 resulting in a rating of 'Partially Degraded.' Classified as a F4/5 channel, this sampling reach is split evenly between silt/clay, sand, gravel and bedrock, each comprising 20-25% of bed substrate. This site received a habitat comparability score of 70.5 with a rating of 'Partially Supporting' due to suboptimal sediment deposition and marginal embeddedness. Due to the depth of the sampling reach, benthic macroinvertebrate sampling was performed along one bank of the reach. There were a total of 22 taxa present in this benthic macroinvertebrate sample, consisting of five EPT taxa and one Ephemeroptera. This sample had 22 total taxa with five EPT taxa and two of those Ephemeroptera. Forty-five percent of the sample consisted of midges while only six percent of individuals were intolerant to urban stressors resulting in a BIBI score of 2.67 with a rating of 'Poor'. Water quality results indicated all parameters were within acceptable COMAR standards.

**09RG-422-F-2016H**

This site is located on the Patuxent River mainstem, just upstream of Washington Boulevard. This reach was classified as a F4/5 channel type with a predominately sand and gravel substrate. Land use in the 87,842-acre drainage area is primarily agricultural (30.8%) and forested land cover (30.0%), with the majority of the remainder as low density residential (17.0%). The overall imperviousness in this drainage area is 9.5%, which is above average for the subwatershed. Because of a general lack of riffles and a minimal riparian zone on the right bank, this site received an RBP habitat assessment score of 60.5 with a rating of 'Partially Supporting.' For PHI, a score of 49.5 and a rating of 'Severely Degraded' was given. Water quality results indicated no parameters that exceeded acceptable COMAR standards. Due to the depth of the sampling reach, benthic macroinvertebrate sampling was performed entirely along one bank of the reach. There were a total of 31 taxa in the sample, the second most taxa present within all samples in the Rocky Gorge subwatershed. Within the benthic sample, five EPT taxa and three Ephemeroptera taxa were present. However, this site had a low percentage of individuals intolerant to urban stressors (7%) and a high percentage (58%) of individuals of the Chironomidae family (midges). Because of the low percentage of intolerant species, this site received a BIBI score of 2.67 and a biological rating of 'Poor.'

**09RG-426-F-2016J**

This sampling reach is located in a fourth-order section of the Patuxent River mainstem, upstream of site 09RG-422-F-2016H. Similar to site 09RG-422, the predominant land use for the 87,801 acre drainage area of this site is agriculture (30.8%) followed by forested land cover (30.0%), and low density residential (17.1%), which resulted in 9.5% imperviousness. This reach was classified as an

F4/5 channel and the substrate was dominated by gravel and sand with some silt/clay particles. Because this site was located in the middle of a large pool feature, the lack of riffles present resulted in a habitat assessment comparability score of 59.0 with 'Non-supporting' classification. A PHI score of 56.4 and rating of 'Degraded' was given to this site. Based on the BIBI score of 2.67, this site was given a 'Poor' biological condition rating. In this benthic macroinvertebrate sample, 33 taxa were present, the most of all Rocky Gorge watershed sites. Of the 33 taxa, eight were EPT taxa, one of which was Ephemeroptera. Individuals of the Chironomidae family (midges) made up 53% of the sample, and individuals intolerant to urban stressors accounted for only twelve percent of the sample. Water quality results indicated all parameters were within acceptable COMAR standards.

### ***3.1.2 Hammond Branch***

All ten sites sampled in 2016 within the Hammond Branch PSU were on first order streams as defined by the NHD stream layer. The field QC sample was collected immediately upstream of site 14HB-123-F-2016I. RBP habitat assessment scores ranged from 41.0%, with a classification of 'Not Supporting' to 78.0% and a classification of 'Supporting'. The mean RBP habitat score was 57.5 with a rating of 'Non-Supporting.' All sites were considered characteristic of piedmont streams and were assessed using the piedmont BIBI. There were only three sites that received biological condition ratings of 'Fair', with scores ranging from 3.00 to 3.33. The other seven sites received "Poor" scores that ranged from 2.00 to 2.67. The mean BIBI score was 2.70, with an average biological condition rating of 'Poor.' Stream reaches were classified as either B, C, G, E or F channels, with sand, gravel, or cobble dominated substrates. A summary of the results for the Hammond Branch subwatershed is found in Figure 5 and Table 9.

#### **Hammond Branch Site Descriptions:**

**14HB-101-R-2016A** This site is located on Hammond Branch downstream of Crabbury Ct. This sampling reach was classified as a G4/5c channel with gravel and sand substrate. Water quality results indicated no parameters that exceeded acceptable COMAR standards. The land use within the 153-acre drainage area is predominantly low density residential (52.6%) followed by forested land cover (32.1%) and agricultural use (15.3%). The percentage of impervious surface in the drainage area is 8.4%, which is below the subwatershed average of 12.5%. This sampling reach contained few riffles, high embeddedness, and poor vegetative protection. As a result, this site received an RBP habitat score of 65.5 and a rating of 'Partially Supporting.' A PHI score of 64.6 was given to this site, resulting in a rating of 'Degraded.' The BIBI score was 2.67, with a biological rating of 'Poor.' Of the 29 taxa present, only two EPT taxa and no Ephemeroptera were present, with 14% of the sampling comprising individuals intolerant to urban stressors. The majority of the sample (48%) consisted of individuals of the Chironomidae family (midges).

#### **14HB-106-R-2016B**

Located behind Lime Kiln Middle School and Reservoir High school, this sampling reach is a C4/5 channel in a cleared powerline easement. The predominant substrate of this stream is gravel and sand. Poor bank stability, vegetative protection, and riparian zone attributed to the RBP habitat assessment rating of 'Non-supporting' with a score of 54.0. The PHI score was 56.9, resulting in a rating of 'Degraded.' A total of 7.8% of the 1,030 acre drainage area consists of impervious land cover, below the subwatershed average. The dominant land use for this drainage area is low density residential (38.6%) followed by agriculture (36.0%) and forested land cover (17.4%). There were 26 taxa in the benthic macroinvertebrate sample, six of which were EPT taxa and one of which was Ephemeroptera. Fifty-one percent of the individuals in this sample were of the Chironomidae family (midges), while 49% of the sample consisted of clingers and only three percent consisted of individuals intolerant to

urban stressors. Overall, this site received a BIBI score of 2.67 with a narrative rating of 'Poor.' Water quality results indicated all parameters within acceptable COMAR standards.

#### **14HB-107-R-2016C**

This site is located behind Reservoir High school in a powerline clearing. Classified as a C3/5 channel, the dominant substrate for this sampling reach is sand, with an abundance of cobble and silt/clay also present. Of the 1,259 acres, impervious surfaces comprised 9.6% of the drainage area. Agriculture is the predominant land use in this drainage area (38.6%) followed by low density residential (32.9%) and forested land cover (16.0%). Physical habitat was rated as 'Non-supporting' and received a RBP habitat score of 46.5 due to unstable banks and poor vegetative protection and riparian zone width. The lowest PHI score in the 2016 set of sites was given to this site with a score of 33.4 and a rating of 'Severely Degraded.' Water quality results indicated no parameters that exceeded acceptable COMAR standards. There were 23 taxa in this benthic macroinvertebrate sample with four EPT taxa and one Ephemeroptera taxa present. Only one percent of the sample consisted of individuals intolerant to urban stressors and individuals of the Chironomidae family (midges) accounted for 49% of the sample resulting in a score of 2.00 and a corresponding biological condition rating of 'Poor.'

#### **14HB-110-R-2016D**

Located behind Hammond Middle and Elementary schools, this sampling reach was classified as a F4/5 channel with a predominately gravel substrate. At this site, the majority of the surrounding land use in the 2,322-acre drainage area is agriculture (34.2%) followed by low density residential (27.5%) and forested land cover (15.1%). Impervious surface accounted for 16.2% of the drainage area, which is above the subwatershed average. This reach had unstable banks and poor vegetative protection, but with a habitat comparability score of 62.0, this site received a 'Partially Supporting' habitat rating. The PHI score was an 82.1 with a rating of 'Minimally Degraded.' This sampling reach also received a BIBI score of 2.67 and a biological rating of 'Poor.' A total of 28 taxa were in the sample, six of which were EPT taxa and one of which was Ephemeroptera. Individuals of the Chironomidae family (midges) made up the majority of this sample (50%) and only four percent of the sample consisted of individuals intolerant to urban stressors. Water quality results indicated all parameters within COMAR standards.

#### **14HB-114-R-2016E**

This site is located on a highly eroded B5c channel along a powerline clearing, with a predominately sand substrate along with a moderate amount of clay hardpan. Water quality results indicated no parameters that exceeded acceptable COMAR standards. The predominant land use in this drainage area is classified as agriculture (28.7%) with low density residential accounting for 22.4% and forested land cover accounting for 17.8%. The overall imperviousness within the 3,555-acre drainage area is 16.7%, which is above the subwatershed average of 12.5%. Because of marginal and poor scores for habitat, embeddedness, sediment deposition, bank stability, vegetative protection and riparian width, this sampling reach received one of the lowest RBP scores of 42.5 and corresponding rating of 'Non-supporting.' The PHI score was also one of the lowest in the subwatershed at 35.5 which results in a rating of 'Severely Degraded.' Of the 30 taxa present in this benthic macroinvertebrate sample, eight EPT taxa were present, three of which were Ephemeroptera taxa. Additionally, chironomids (midges) accounted for 45% of the sample and 12% consisted of individuals tolerant to urban stressors. This site received the highest BIBI scores within this subwatershed with a score of 3.33 and a narrative rating of 'Fair.'

#### **14HB-116-R-2016F**

This sampling site is located in a forested area behind Promise Ct. with very low flow. The reach was classified as a G6c channel dominated by silt/clay substrate. In the 3,708-acre drainage area to this site, the majority of the surrounding land use is agriculture (29.4%) and low density residential (21.5%), with 19.0% forested land cover. The percentage of impervious surface in the drainage area is 16.4%, which is above the subwatershed average. All water quality parameters were within COMAR limits. As a result of poor habitat, embeddedness, velocity/depth regime, frequency of riffles, and vegetative protection, this site received the lowest RBP score of 41.0 with a rating of 'Non-supporting'. The PHI score of 36.9 and rating of 'Severely Degraded' align with the RBP. This benthic macroinvertebrate sample had a low number of taxa (10) and EPT taxa were entirely absent. Individuals of the Tubificidae family (worms) dominated this sample at 84%, with *Spirosperma* (TV = 6.6) accounting for over a third of the sample. As a result of a large percentage of worms and a complete absence of individuals intolerant to urban stressors, this site received a BIBI score of 2.33 and a narrative rating of 'Poor.'

#### **14HB-119-F-2016G**

This site was located on the edge of a powerline clearing, between agriculture fields and residential homes on Wayneridge St. Classified as an E4/5 channel, the substrate of this sampling reach was predominantly gravel and sand. At 717-acres, this site had the smallest drainage area of the subwatershed. Low density residential land use dominates this drainage area at 37.9%, followed by agriculture (30.5%) and forest (22.8%), which results in 7.5% impervious land cover—the lowest percentage in this subwatershed. No water quality parameters exceeded acceptable COMAR standards. The PHI score was 67.3 with a rating of 'Partially Degraded.' The RBP habitat assessment indicated a 'Partially Supporting' habitat with a score of 61.0. A total of 35 taxa, the highest total taxa value in the subwatershed, were present in this benthic macroinvertebrate sample. Eight EPT taxa and four Ephemeroptera were present. Almost half of this sample consisted of chironomids (midges), accounting for 48% of the sample. Although this site had the most taxa, only eight percent were individuals intolerant to urban stressors. Overall, this sample received one of the highest BIBI scores for this subwatershed of 3.00, with a rating of 'Fair' (tied with site 14HB-121-F-2016H).

#### **14HB-121-F-2016H**

Located in a forested buffer between Graeloch Rd and Bubbling Spring, this sampling reach was classified as a C4/5 channel dominated by gravel with some silt/clay substrate. Water quality results indicated no parameters that exceeded acceptable COMAR standards. While there was marginal bank stability and marginal riffle frequency, this site received a RBP habitat score of 67.0 with a rating of 'Partially Supporting.' A PHI score of 75.6 resulted in a rating of 'Partially Degraded.' In this 2,152-acre drainage area, agriculture was the predominant land use (36.9%) followed by low density residential (27.3%) and 14.4% consisting of forested land cover. The overall impervious drainage is 16.2%, which exceeds the subwatershed average. This site received a BIBI score of 3.00 with a narrative rating of 'Fair,' which is the 2<sup>nd</sup> highest rating in the subshed (tied with site 14HB-119-F-2016G). There were 25 taxa in this benthic macroinvertebrate sample, five of which were EPT taxa but with only two Ephemeroptera taxa present. The Chironomidae family (midges) made up 48% of the sample, while only five percent of this sample consisted of individuals intolerant to urban stressors.

#### **14HB-123-F-2016I**

This site is located in a riparian zone between Stebbing Way and Steeple Ct. This sampling reach was classified as a C3 channel. Cobble is the dominant substrate type for this channel. At 4,088 acres, this is the largest drainage area of this subwatershed. Although 29.4% of the drainage area is agriculture and 19.0% is forested land cover, combined low/ medium/high density residential accounts for over 36% of the drainage area. As a result, the drainage area has 16.8% impervious surface, which is the

highest in the subwatershed. RBP Habitat was rated as ‘Supporting’ with a score of 78.0. This site was the only location in this subwatershed that received a ‘Supporting’ habitat condition rating. The PHI score was also a 78.0, which resulted in a rating of ‘Partially Degraded.’ While there was a moderately high number of total taxa (27), there was a low number of EPT taxa present (four), and only two Ephemeroptera taxa present in the benthic macroinvertebrate sample. Additionally, chironomids (midges) dominated this sample at 55%. Seventeen percent of this sample comprised of individuals intolerant to urban stressors. This site received a BIBI score of 2.67, which resulted in a ‘Poor’ biological condition rating. A QC sample was completed in the adjacent 75-meters reach upstream of this site, where water conditions and habitat resembled the original reach. The QC reach received a BIBI score of 2.00, resulting in a ‘Poor’ biological condition rating. RBP habitat was also conducted at the QC site which received a score of 76.5 and a rating of ‘Supporting.’

#### **14HB-125-F-2016J**

Located in a powerline clearing, between a newly developed residential community and Reservoir high school. This sampling reach was classified as a C4/5 channel with a mix of sand and gravel substrates. Water quality results indicated all parameters within acceptable COMAR standards. Because of suboptimal habitat and embeddedness along with marginal sediment deposition, bank stability and vegetative protection, this reach received a habitat comparability score of 57.5 with a ‘Non-supporting’ classification. A PHI score of 49.6 and corresponding ‘Severely Degraded’ rating was applied to this reach. Over one-third of the land use in the 1,251-acres draining to the site is agricultural land use (38.7%), with an additional 33.1% as low density residential and 15.6% as forested land cover. The percentage of impervious surface in the drainage area is 9.6%, which is below the subwatershed average. Of the 28 total taxa identified in this sample, only four were EPT taxa and two were Ephemeroptera taxa. Individuals of the Chironomidae family (midges) dominated this sample at 53%, with *Cricotopus/Orthocladius* (TV = 7.7) accounting for 26% of the sample. Only five percent of this sample consisted of individuals intolerant to urban stressors. The site received a BIBI score of 2.67 with a corresponding biological rating of ‘Poor.’

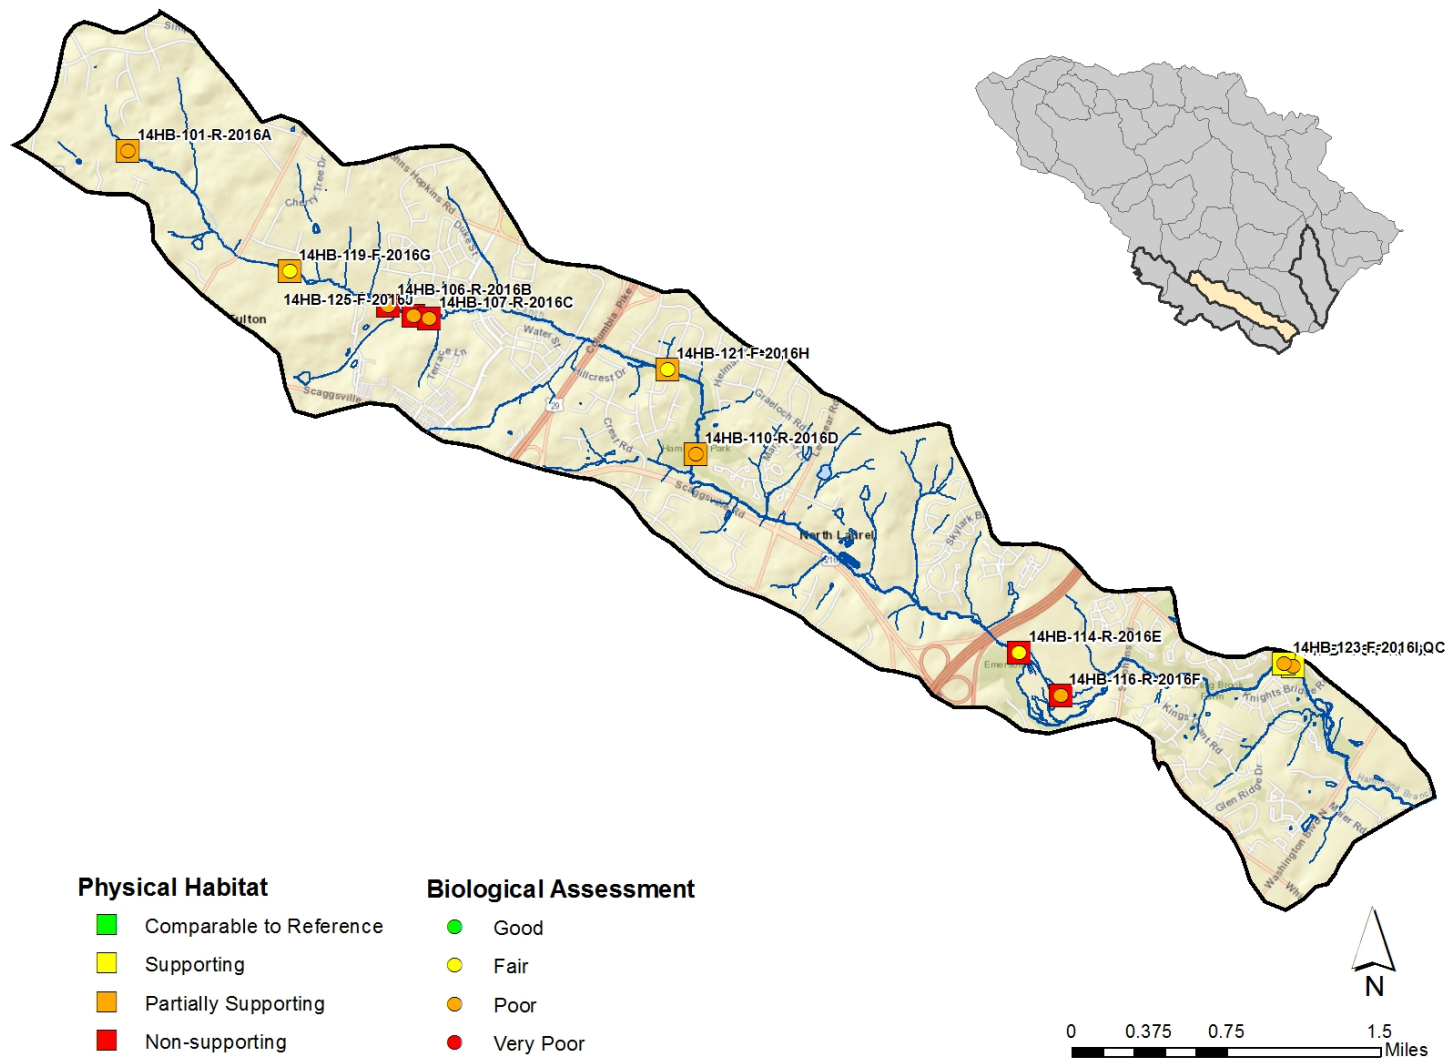

Figure 5 - Hammond Branch PSU Sampling Results

**Table 9 - Hammond Branch Summary**

| Site ID            | Drainage Area (ac) | Impervious Surface Percent | BIBI Score | BIBI Rating | RBP Comparability Score | RBP Rating           | PHI Score | PHI Rating         | Rosgen Channel Type |
|--------------------|--------------------|----------------------------|------------|-------------|-------------------------|----------------------|-----------|--------------------|---------------------|
| 14HB-101-R-2016A   | 153                | 8.4                        | 2.67       | Poor        | 65.5                    | Partially Supporting | 64.6      | Degraded           | G4/5c               |

\*QC sampling was conducted at this site

### ***3.1.3 Dorsey Run***

All ten sites sampled in the Dorsey Run subwatershed in 2016 were located on first-order streams as defined by the NHD stream layer. The field QC sample was collected at site 15DR-123-F-2016I. All stream reaches were classified as C or F channels, with sand or gravel dominated substrates. A summary of the results for the Dorsey Run subwatershed is presented in Figure 6 and Table 10.

Three sites within the Dorsey Run PSU were rated as ‘Supporting’ and five sites were rated as ‘Partially Supporting’ based on the RBP habitat assessment scores. The mean RBP habitat comparability score of 66.9 for the subwatershed resulted in a ‘Partially Supporting’ rating.

Eight of the ten sites sampled in the Dorsey Run subwatershed received biological condition ratings of ‘Very Poor.’ The remaining two sites received ‘Poor’ biological ratings. BIBI scores ranged from a low of 1.00 to 2.33, which resulted in a mean BIBI score of 1.40 and an overall biological condition rating of ‘Very Poor’ for the subwatershed.

#### **Dorsey Run Site Descriptions:**

##### **15DR-102-R-2016A**

This site runs parallel to railroad tracks with a large bridge culvert (Dorsey Run Road) spanning the middle portion of the reach. The stream was classified as a F5 channel with sand as the dominant substrate. A high measurement of conductivity (762.0  $\mu\text{S}/\text{cm}$ ) was observed at this site, but water quality results indicated no parameters that exceeded acceptable COMAR standards. Of the 4,154-acre drainage area, the dominant land use is commercial and industrial (42.%) followed by forested land cover (23.4%). Low, medium, and high density residential land use, when combined, account for nearly 20% of the drainage area, contributing to an impervious percentage of 36.8% that exceeds the subwatershed average of 33.2%. This sampling reach received the lowest RBP habitat score of 41.5 and a rating of ‘Non-supporting’ due to poor instream habitat, embeddedness, sediment deposition, and riffle frequency. The PHI also shows a ‘Severely Degraded’ channel with a score of 41.5, the lowest in the subwatershed. The BIBI score of 2.33 was the highest in Dorsey Run, although the biological condition was rated as ‘Poor.’ Of the 20 total taxa identified in the sample, only two were EPT taxa and two Ephemeroptera taxa were present. Fifty-six individuals (or 57%) were Oligochaeta (worms) with tolerance values ranging from 8.4 to 9.1. Only 11% of the individuals were intolerant to urban stressors.

##### **15DR-104-R-2016B**

This site is located on a F4/5 channel with predominately gravel and sand substrate. The reach runs in a forested area between a mobile home community on Inwood Ct. and railroad tracks near Tar Bay Dr. Water quality results indicated no parameters that exceeded acceptable COMAR standards, but the site did have high specific conductivity (787.0  $\mu\text{S}/\text{cm}$ ). Because of marginal scores for instream habitat, embeddedness, sediment deposition, and bank stability this site received a habitat assessment score of 59.0 and a ‘Non-supporting’ classification. A PHI score 64.9 resulted in a ‘Degraded’ condition rating. The dominant land use in the 1,357-acres drainage area is commercial and industrial (40.2% ) followed by forested land cover (31.8%). Impervious surface accounted for 30.9% of the drainage area, which is slightly below the subwatershed average of 33.2%. There were 14 total taxa identified in the benthic macroinvertebrate sample, although EPT taxa were absent. Ephemeroptera and individuals intolerant to urban stressors were also absent from this sample. Individuals of the Chironomidae family (midges) dominated this sample at 66%. Only seven percent of the sample consisted of clingers. As a result, this site received the lowest BIBI score possible (1.00) with a corresponding biological rating of ‘Very Poor.’

**Figure 6 - Dorsey Run PSU Sampling Results**

### **15DR-109-R-2016C**

This site is located upstream of a stormwater management pond which drains office buildings and parking lots off of Benjamin Franklin Dr. The site is also upstream of a ramp from Route 175 to I-95 S. While no water quality parameters exceeded acceptable COMAR standards, high specific conductivity (821  $\mu\text{S}/\text{cm}$ ) was measured at this site. With a predominantly gravel and sandy substrate, the sampling reach was classified as a C4/5 channel. Optimal habitat, sediment deposition, riffle frequency, bank stability, and vegetative protection led to the highest RBP habitat score in the watershed (80.5) and a habitat rating of ‘Supporting.’ The PHI score was 79.3, the highest in the subwatershed, which resulted in a rating of ‘Partially Degraded.’ This site had a drainage area of 1,661-acres with 35.9% classified as commercial and industrial land use, 35.6% as combined low, medium, and high density residential, and 18.3% as forested land cover. Impervious surface percentage exceeded the subwatershed average at 36.7%. Of the 20 total taxa identified, four EPT taxa were present in the sample, one of which was Ephemeroptera. Individuals intolerant to urban stressors accounted for just one percent of the sample while 11% of the sample consisted of clingers. Eighty-four percent of the sample was made up of Chironomids (midges). Based on the BIBI score of 1.33, this site was given a ‘Very Poor’ biological condition rating.

### **15DR-111-R-2016D**

This site is located approximately 800 feet upstream from 15DR-109-R-2016C on a F4/5 channel with a gravel and sand substrate. Optimal sediment deposition, riffle frequency, and bank stability led to a habitat assessment rating of ‘Supporting’ with a percent comparability score of 76.0. The predominant land use in the 1.636-acre drainage area is commercial and industrial (36.4%) followed by medium density residential (19.8%) and forested land cover (17.6%). Overall, the drainage area has 37.1% impervious surfaces, which is above the average for the Dorsey Run subwatershed. The benthic macroinvertebrate sample was dominated by individuals of the Chironomidae family (79%), with *Cricotopus/Orthocladius* (TV = 7.7) accounting for 41% of the sample. There were 18 total taxa in this sample with three EPT taxa and only one Ephemeroptera taxa. Only two percent of the individuals were considered intolerant to urban stressors—resulting in a BIBI score of 1.33 and a biological condition rating of ‘Very poor.’ While, water quality results indicated no parameters that exceeded acceptable COMAR standards, this site had the highest conductivity readings in this subwatershed at 833.0  $\mu\text{S}/\text{cm}$ .

### **15DR-112-R-2016D**

This site is located upstream of John McAdams Dr. and downstream of Route 175. High specific conductivity (819  $\mu\text{S}/\text{cm}$ ) was recorded at this site, but the remaining water quality parameters were within acceptable COMAR standards. Classified as a F4/5 channel, the substrate of this sampling reach was dominated by gravel. This sampling reach received an RBP habitat score of 70.5 and rating of ‘Partially Supporting.’ The 1,464-acre drainage area is predominantly commercial and industrial land use (33.4%) with low and medium density residential collectively accounting for over 40% of the land use, resulting in 36.9% impervious surface. There were 19 total taxa in this sample, three of which were an EPT taxa. There was one Ephemeroptera taxa and two total individuals intolerant to urban stressors identified in this sample. Individuals of the Chironomidae family (midges) dominated this sample at 71%. This site received a BIBI score of 1.33 with a corresponding biological condition rating of ‘Very Poor.’

**Table 10 - Dorsey Run Summary**

| Site ID            | Drainage Area (ac) | Impervious Surface Percent | BIBI Score | BIBI Rating | RBP Comparability Score | RBP Rating           | PHI Score | PHI Rating         | Rosgen Channel Type |

\*QC sampling was conducted at this site

### **15DR-116-R-2016F**

Located in a densely a narrowly forested area behind Distant Rock Path, this sampling reach was classified as a F4/5 channel with a predominately sand and gravel substrate. High average conductivity (617.4  $\mu\text{S}/\text{cm}$ ) was measured at this site, but water quality results indicated all parameters within acceptable COMAR standards. This site received an RBP habitat assessment score of 73.0 and a rating of 'Partially Supporting.' Land use in the 511-acre drainage area is primarily medium density residential (34.0%) and high density residential (28.0%), with 13.1% forest land cover. The overall imperviousness is 25.0%, well below the subwatershed average of 33.2%. There were 18 total taxa identified in the benthic macroinvertebrate sample, two of which were EPT taxa. Individuals of the Chironomidae family (midges) dominated this sample at 82%, with *Cricotopus/Orthocladius* (TV = 7.7) comprising 32% of the sample. There was one Ephemeroptera taxa and four individuals intolerant to urban stressors identified in the sample. Only 11% of the sample consisted of clingers. As a result, this site received a BIBI score of 1.33 with a biological condition rating of 'Very Poor.'

### **15DR-119-F-2016G**

This site is located behind the apartment complex on Crestmount Rd. The reach was classified as a F4/5 channel type with a predominantly gravel substrate. High specific conductivity (655  $\mu\text{S}/\text{cm}$ ) was measured at this site, but water quality results indicated all parameters within acceptable COMAR standards. The habitat assessment indicated a 'Supporting' habitat with a score of 78.0 due to optimal sediment deposition and riffle frequency, with all other parameters in the suboptimal range. Within the 2,053-acre drainage area, the predominant surrounding land use is commercial and industrial (30.9%), followed by forest (20.8%) and medium density residential (19.0%). Overall, the drainage area has 34.0% impervious surface—slightly above the subwatershed average. The BIBI score for this site was 1.33, resulting in a narrative rating of 'Very Poor.' Of the 21 total taxa identified in this sample, three were EPT taxa, and only four percent of the sample consisted of individuals intolerant of urban stressors. Ephemeroptera taxa were completely absent. Individuals of the Chironomidae family (midges) dominated this sample at 77%, with *Cricotopus/Orthocladius* (TV = 7.7) accounting for 36% of the sample. A QC site was completed immediately upstream of this site and received a slightly lower habitat assessment score of 74.5 with the rating of 'Partially Supporting.' The QC site had 20 total taxa with two EPT, no Ephemeroptera, and five percent individuals intolerant to urban stressors identified. Ultimately, the QC site received the same BIBI score as 15DR-119-F-2016G (1.33) with a rating of 'Very Poor'.

### **15DR-121-F-2016H**

Located approximately 600 feet upstream of 15DR-102-R-2016A, this sampling reach is classified as a F4/5 channel with a predominately gravel substrate. Water quality results indicated no parameters that exceeded acceptable COMAR standards, but did show elevated conductivity (679  $\mu\text{S}/\text{cm}$ ). The drainage area to this site is 4,073 acres and is comprised primarily of commercial and industrial (41.3%), forest (23.3%) and medium density residential (11.2%). Imperviousness in the drainage area is 36.4%, above the subwatershed average of 33.2%. Because of marginal scores for embeddedness, sediment deposition, channel flow status, and bank stability, this site received an RBP habitat comparability score of 64.5 and a rating of 'Partially Supporting.' There were 13 total taxa in this sample, one of which was an EPT taxon and in the order Ephemeroptera. Only one individual intolerant to urban stressors was identified in this sample. Individuals of the Chironomidae family (midges) dominated this sample at 70%. This site received the lowest possible BIBI score of 1.00 with a corresponding biological rating of 'Very Poor'.

### **15DR-123-F-2016I**

This reach runs parallel with a railroad track and is located behind Cherry Hill Construction Company. While no water quality parameters exceeded acceptable COMAR standards, conductivity values were elevated (748  $\mu\text{S}/\text{cm}$ ). The stream was classified as a F4/5 channel with gravel and sand as the dominant substrates. Of the 2,475-acres draining to this site, 38.5% is impervious, which is the highest in the subwatershed. The predominant land use for the drainage area is commercial and industrial (39.1%) followed by forested land cover (18.7%) and medium density residential (16.4%). The RBP habitat assessment resulted in a comparability score of 62.0, or 'Partially Supporting', with marginal scores received for embeddedness, sediment deposition, and channel flow status. This sampling reach received a BIBI score of 1.67 and a biological rating of 'Very Poor.' There were 17 total taxa in the sample with no EPT taxa, no Ephemeroptera taxa, and only one scraper present. Clingers accounted for 15% of the sample with only three percent of the sample consisting of individuals intolerant to urban stressors. Forty-four percent of the sample consisted of Chironomids (midges) and 46% were Oligochaetes (worms).

### **15DR-125-F-2016J**

This site is located on Dorsey Run just upstream of the Snowden River Parkway culvert. The reach was classified as a C4/5 channel with a predominately sand and gravel substrate. While no water quality parameters exceeded acceptable COMAR standards, slightly elevated conductivity (386  $\mu\text{S}/\text{cm}$ ) was measured at this site but was the lowest of all reaches in the Dorsey Run subwatershed. The RBP habitat assessment resulted in a comparability score of 64.0, or 'Partially Supporting', with marginal scores received for instream habitat, embeddedness, velocity/depth regime, sediment deposition, and channel flow status. At 125-acres, this is the smallest drainage area in the subwatershed with 19.7% impervious surface, the lowest in the subwatershed. Land use in the drainage area is primarily medium density residential (54.7%) followed by high density residential (15.6%) and forested land cover (13.5%). Of the 22 total taxa identified in the benthic macroinvertebrate sample, two EPT taxa were present, but no Ephemeroptera were found. Only eight percent individuals intolerant to urban stressors were present. A total of 87% of the sample was dominated by Chironomids (midges). The overall BIBI score was 1.33, resulting in a biological condition rating of 'Very Poor.'

## **4 Discussion and Comparison**

### **4.1 Discussion**

#### **4.1.1 2016 Assessment Results**

##### *Bioassessment*

Biological and physical habitat assessment results for 2016 in Rocky Gorge, Hammond Branch, and Dorsey Run indicate subwatersheds that are moderately to severely impaired. Only two of the thirty benthic macroinvertebrate samples received a rating of 'Good' and five received a 'Fair' rating. The remaining sites (77%) were rated as either 'Poor' or 'Very Poor.' Site 09RG-102-R-2016A and 09RG-104-R-2016B were the only sites to receive a biological condition rating of 'Good.' No sites received a 'Good' or 'Fair' biological condition ratings in the Dorsey Run subwatershed.

##### *Physical Habitat*

RBP habitat assessment results indicate average subwatershed physical habitat conditions that were 'Partially Supporting' (Rocky Gorge, Dorsey Run) and 'Non-supporting' (Hammond Branch). Only four sites received 'Supporting' physical habitat ratings (i.e., 14HB-123-F-2016I, 15DR-109-R-

2016C, 15DR-111-R-2016D and 15DR-119-F-2016G) located within the Hammond Branch and Dorsey Run subwatersheds.

#### *Water Quality*

All but one site (09RG-119-F-2016G) showed pH readings within the allowable COMAR range. Specific conductivity was elevated at many sites throughout the watersheds with values ranging from 142 to 833  $\mu\text{S}/\text{cm}$ . A site-by-site breakdown of field-measured water quality parameters is included in Appendix B. While no COMAR standard for conductivity currently exists, a threshold for biological impairment in Maryland streams has been established at 247  $\mu\text{S}/\text{cm}$  (Morgan et al., 2007). Thus, PSUs with mean values exceeding 247  $\mu\text{S}/\text{cm}$  are not only indicative of increased anthropogenic disturbance, but also likely to see degraded biological conditions. Within this range of values, less than one third (23%) sampled in 2016 had a value less than 200  $\mu\text{S}/\text{cm}$ . Average subwatershed conductivity values were 213  $\mu\text{S}/\text{cm}$ , 307  $\mu\text{S}/\text{cm}$ , and 725  $\mu\text{S}/\text{cm}$ , for Rocky Gorge, Hammond Branch, and Dorsey Run, respectively.

Specific conductivity is related to the type and concentrations of inorganic ions in solution. Natural sources within a watershed can include salt from poorly drained soils, salt from ground water, and erosion from geologic formations of marine origin. Increased stream inorganic ion concentrations (i.e., conductivity) in urban systems typically results from runoff over impervious surfaces, passage through pipes, and exposure to other infrastructure (Cushman, 2006). Roadway pollutants tend to concentrate along the edge of a road, making them susceptible to runoff to streams from rainfall or snow melt and flow-off from wind or vehicle turbulence. While elevated conductivity may not directly affect stream biota, its constituents (e.g., chloride, metals, and nutrients) may be present at levels that can cause considerable biological impairment.

#### *Geomorphology*

The geomorphic assessment results indicate a variable system. Less than half of the channels sampled throughout the subwatersheds were classified as stable type B or C channels, the majority were classified as unstable, incised F channels. Gravel and sand were the dominant substrate types in the majority of sampling reaches, however silt/clay and cobble dominate streams were also present.

#### *Imperviousness*

The average percentage of impervious area in the Rocky Gorge, Hammond Branch, and Dorsey Run subwatersheds is 8.8%, 12.5%, and 33.2%, respectively. Imperviousness for the areas draining to each sampling site range from 7.5% in Hammond Branch to 38.5% in Dorsey run (see Appendix A for impervious values). The benthic community in a freshwater stream can be adversely affected by impervious cover and associated runoff at values as low as 10% (CWP, 2003). A statistical correlation between imperviousness and the BIBI was identified and is discussed in the following section.

#### *Results Correlations*

The Pearson correlation coefficient measures the linear association between two variables. Values of the coefficient range from -1 to 1. Negative values indicate an inverse relationship between the two values (i.e., when one variable increases the other decreases), while positive values indicate a positive relationship (i.e., both variables increase). The Pearson correlation coefficient indicates the strength of the association, with larger absolute values indicating stronger associations between the two variables. The significance level is a measure of the likelihood that the two variables are related, with smaller values indicating a stronger likelihood of relation. A significance level of 0.05 is typically used as a cutoff for strong correlations. The interpretation of a correlation is somewhat arbitrary, especially as values move away from +/- 1. Table 11 includes Pearson correlation coefficients and significance values. Figures 7 through 9 provide a visual display of the relationships between data variables and the best fit line, including  $R^2$  values, associated with the correlation.

Pearson correlations between the BIBI scores and two parameters (percent imperviousness and specific conductivity) showed highly significant relationships. The percentage of imperviousness to each sampling site indicates a strong negative relationship (correlation coeff.= -0.648,  $p < 0.001$ ) to BIBI scores, suggesting biological condition decreases with increased watershed imperviousness (Figure 7.)

**Figure 7 - Relationship between the Benthic Index of Biotic Integrity (BIBI) and impervious surface in PSUs sampled during 2016 Howard County Biological Monitoring**

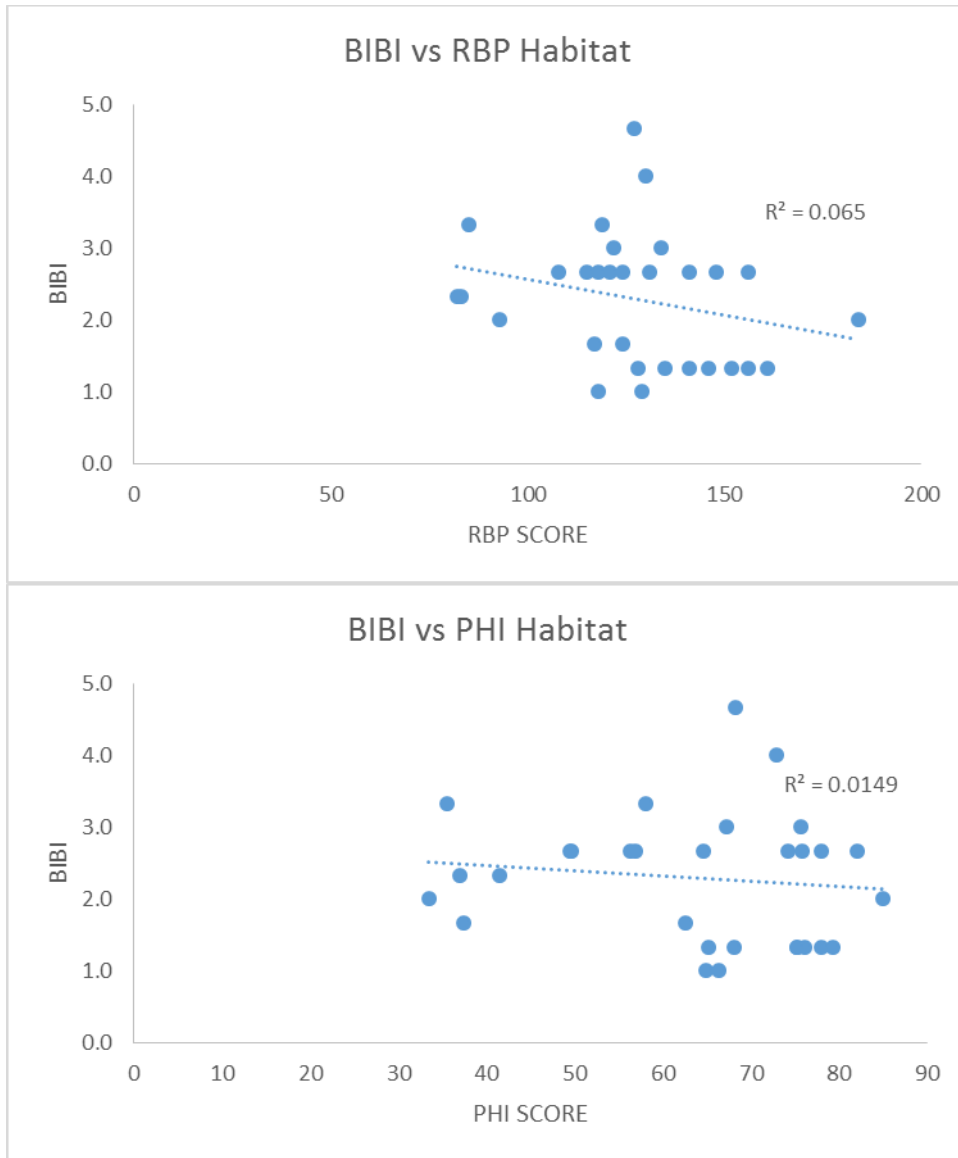

Specific conductivity and BIBI scores also showed a strong negative correlation (correlation coeff.= -0.596,  $p = 0.001$ , Figure 8). These results support the notion that overall water quality and biological health are likely being affected by the amount of development, and hence imperviousness, in the watershed. These findings are in concurrence with the Impervious Cover Model (CWP, 2003) which suggests that overall stream quality decreases with increased watershed impervious cover. A strong correlation was also observed between impervious percent and specific conductivity (correlation coeff.= 0.982,  $p < 0.0001$ ), suggesting that increased conductivity is due in large part to urban runoff.

**Figure 8 - Relationship between the Benthic Index of Biotic Integrity (BIBI) and specific conductivity in PSUs sampled during 2016 Howard County Biological Monitoring**

The correlation with RBP habitat scores and BIBI scores (correlation coeff.= -0.255, p = 0.174) was not significant, nor was the correlation between PHI scores and BIBI (correlation of -0.122, p = 0.521) (Figure 9) suggesting that physical habitat assessments are not the best predictor of biological condition in these watersheds. Water quality and imperviousness are better predictors of biological condition.

**Figure 9 - Relationship between the Benthic Index of Biotic Integrity (BIBI) and physical habitat in PSUs sampled during 2016 Howard County Biological Monitoring**

**Table 11 - Pearson Correlations**

|                           |              | RBP Habitat | PHI Habitat        | Specific Conductance | Percent Impervious |

#### 4.1.2 Comparison of 2003, 2009, and 2016 Bioassessment data

##### BIBI

A summary of the results for 2003, 2009 and 2016 biological index data is shown in Table 12, and a box plot comparing BIBI scores for each subwatershed is displayed in Figure 10. It should be noted that current BIBI calculation methods were used for all rounds. An Analysis of Variance (ANOVA) was performed to evaluate differences in mean BIBI scores amongst the years. Significance testing was performed using Tukey's HSD (Honestly Significant Difference) test with a confidence interval of 95%. Results of Tukey's HSD test are presented in Table 13.

**Table 12 - Comparison of 2003, 2009, and 2016 BIBI Data**

| Sampling Year | Patapsco Subwatershed | Number of sites sampled | Min. BIBI | Max. BIBI | Median BIBI | Mean BIBI | Narrative Rating | Standard Deviation |
|---------------|-----------------------|-------------------------|-----------|-----------|-------------|-----------|------------------|--------------------|
| 2003          | Rocky Gorge           | 10                      | 1.33      | 4.00      | 3.00        | 2.83      | Poor             | 0.84               |
|               | Hammond Branch        | 10                      | 1.00      | 4.00      | 3.00        | 2.93      | Poor             | 0.80               |
|               | Dorsey Run            | 10                      | 1.67      | 3.00      | 2.17        | 2.20      | Poor             | 0.48               |
| 2009          | Rocky Gorge           | 10                      | 1.67      | 4.33      | 3.00        | 2.94      | Poor             | 0.86               |
|               | Hammond Branch        | 10                      | 1.33      | 2.67      | 2.17        | 2.10      | Poor             | 0.52               |
|               | Dorsey Run            | 10                      | 1.00      | 2.14      | 1.17        | 1.40      | Very Poor        | 0.49               |
| 2016          | Rocky Gorge           | 10                      | 1.33      | 4.67      | 2.67        | 2.77      | Poor             | 1.02               |
|               | Hammond Branch        | 10                      | 2.00      | 3.33      | 2.67        | 2.70      | Poor             | 0.37               |
|               | Dorsey Run            | 10                      | 1.00      | 2.33      | 1.33        | 1.40      | Very Poor        | 0.38               |

**Figure 10 - Comparison of 2003, 2009, and 2016 BIBI scores.**

Results from the Round 1 assessment (2003) indicated that the Rocky Gorge subwatershed was in a ‘Poor’ overall biological condition, according to the updated BIBI scores (BIBI =  $2.83 \pm 0.84$ ). Round Two results (2009) show a similar ‘Poor’ biological condition (BIBI =  $2.94 \pm 0.86$ ). Round 3 results also show a ‘Poor’ biological condition (BIBI =  $2.77 \pm 1.02$ ) and a small decline in score compared to the 2009 score. Tukey’s HSD test showed that the three Rounds were not significantly different from each other (Table 13).

In the Hammond Branch subwatershed, the mean BIBI score declined significantly between 2003 (BIBI =  $2.93 \pm 0.80$ ) and 2009 (BIBI =  $2.10 \pm 0.52$ ), although the narrative rating of ‘Poor’ did not change (Hill and Crunkleton, 2009). Results from 2016 show an increase (BIBI =  $2.70 \pm 0.37$ ) that is closer to what was observed in 2003. Tukey’s HSD test showed a significant difference between 2003 and 2009, but not between 2009 and 2016 or 2003 and 2016 (Table 13).

**Table 13. Tukey (HSD) / Analysis of the differences between years with a confidence interval of 95%**

| Subwatershed   | Contrast     | Difference | Standardized difference | Critical value | Pr > Diff | Significant |
|----------------|--------------|------------|-------------------------|----------------|-----------|-------------|
| Rocky Gorge    | 2009 vs 2016 | 0.17       | 0.42                    | 2.48           | 0.91      | No          |
|                | 2009 vs 2003 | 0.10       | 0.26                    | 2.48           | 0.96      | No          |
|                | 2003 vs 2016 | 0.07       | 0.16                    | 2.48           | 0.99      | No          |
| Hammond Branch | 2003 vs 2009 | 0.83       | 3.16                    | 2.48           | 0.01      | Yes         |
|                | 2003 vs 2016 | 0.23       | 0.88                    | 2.48           | 0.65      | No          |
|                | 2016 vs 2009 | 0.60       | 2.27                    | 2.48           | 0.08      | No          |
| Dorsey Run     | 2003 vs 2016 | 0.80       | 3.97                    | 2.48           | 0.00      | Yes         |
|                | 2003 vs 2009 | 0.80       | 3.95                    | 2.48           | 0.00      | Yes         |
|                | 2009 vs 2016 | 0.00       | 0.02                    | 2.48           | 1.00      | No          |

Tukey's d critical value: 3.507

Similar to Hammond Branch, the Dorsey Run subwatershed saw BIBI scores significantly decline between 2003 (BIBI =  $2.20 \pm 0.48$ ) and 2009 (BIBI =  $1.40 \pm 0.49$ ), dropping a full narrative rating to ‘Very Poor’ biological condition (Hill and Crunkleton, 2009). In 2016, the mean BIBI was calculated at  $1.40 \pm 0.38$ , the same as 2009, and also received a ‘Very Poor’ biological condition rating. Tukey’s HSD test showed a significant difference between 2003 and 2009, and 2003 and 2016, but not between 2009 and 2016 (Table 13).

*RBP Physical Habitat Assessment*

A summary of the results for 2003, 2009 and 2016 RBP physical habitat assessment data is shown in Table 14, and a box plot comparing RBP percent comparability scores for each subwatershed is displayed in Figure 11. An Analysis of Variance (ANOVA) was performed to evaluate differences in mean RBP scores amongst the years. Significance testing was performed using Tukey’s HSD (Honestly Significant Difference) test with a confidence interval of 95%. Results of Tukey’s HSD test are presented in Table 14.

Results from the Round 1 assessment (2003) indicated that the Rocky Gorge subwatershed was ‘Non-Supporting’ (RBP =  $57.2 \pm 9.7$ ). Round 2 results (2009) show improved habitat conditions of ‘Partially Supporting’ (RBP =  $61.7 \pm 5.1$ ), and Round 3 results also show a ‘Partially Supporting’ habitat condition (RBP =  $67.0 \pm 10.2$ ). Tukey’s HSD test showed a significant difference between 2003 and 2016, but not between 2009 and 2003 or 2009 and 2016 (Table 14).

**Table 14 - Comparison of 2003, 2009, and 2016 RBP Physical Habitat Assessment Data**

| Sampling Year | Patapsco Subwatershed | Number of sites Assessed | Min. RBP % | Max. RBP % | Median RBP % | Mean RBP % | Narrative Rating     | Standard Deviation |
|---------------|-----------------------|--------------------------|------------|------------|--------------|------------|----------------------|--------------------|
| 2003          | Rocky Gorge           | 10                       | 44         | 73         | 58           | 57.2       | Non-Supporting       | 9.7%               |
|               | Hammond Branch        | 10                       | 44         | 71         | 58           | 57.6       | Non-Supporting       | 8.1%               |
|               | Dorsey Run            | 10                       | 34         | 73         | 49           | 50.2       | Non-Supporting       | 12.5%              |
| 2009          | Rocky Gorge           | 10                       | 56         | 72         | 60           | 61.7       | Partially Supporting | 5.1%               |
|               | Hammond Branch        | 10                       | 38         | 80         | 62           | 62.8       | Partially Supporting | 13.3%              |
|               | Dorsey Run            | 10                       | 35         | 65         | 57           | 53.5       | Non-Supporting       | 9.8%               |
| 2016          | Rocky Gorge           | 10                       | 59         | 92         | 64           | 67.0       | Partially Supporting | 10.2%              |
|               | Hammond Branch        | 10                       | 41         | 78         | 59           | 57.5       | Non-Supporting       | 11.7%              |
|               | Dorsey Run            | 10                       | 42         | 81         | 68           | 66.9       | Partially Supporting | 11.5%              |

Results from the Round 1 assessment (2003) indicated that the Hammond Branch subwatershed was ‘Non-Supporting’ (RBP =  $57.6 \pm 8.1$ ). Round 2 results (2009) show improved habitat conditions of ‘Partially Supporting’ (RBP =  $62.8 \pm 13.3$ ), while Round Three results showed a decline back to ‘Non-Supporting’ habitat condition (RBP =  $57.5 \pm 11.7$ ). Tukey’s HSD test showed that the three Rounds were not significantly different from each other (Table 14).

The Dorsey Run subwatershed saw ‘Non-Supporting’ RBP conditions in both 2003 (RBP =  $50.2 \pm 12.5$ ) and in 2009 (RBP =  $53.5 \pm 9.8$ ). However, RBP conditions increased from ‘Non-Supporting’ in 2009 to ‘Partially Supporting’ in 2016 (RBP =  $66.9 \pm 11.5$ ). Tukey’s HSD test showed a significant difference between 2003 and 2016 and 2009 and 2016, but not between 2009 and 2003 (Table 14).

Figure 11 - Comparison of 2003, 2009 and 2016 RBP Physical Habitat Assessment scores.

## 5 Conclusion and Recommendations

This report is the final annual report that concludes Round 3 (2012-2016) of the Howard County Biological Monitoring and Assessment Program. These conclusions and recommendations provide context for interpreting results and identifying possible future revisions.

Results of the 2016 assessment indicate impaired biological conditions in all three watersheds, and statistically significant decreases in mean BIBI scores were observed in Dorsey Run since Round One. Physical habitat scores also showed some statistically significant changes, however, they do not match the trends observed in the BIBI results. Decreases in RBP scores were not observed where decreases in biological condition occurred, which suggests that changes in water quality and/or quantity may be responsible for the impairments. Furthermore, strong correlations were found between biological condition and both imperviousness and conductivity, strengthening the weight of evidence toward water quality/hydrologic stressors.

Increasing residential and commercial development in Howard County is leading to rising levels of impervious surface. Continued monitoring is critical to determining whether these changes in land use will detrimentally impact the health of the watersheds, and more importantly, to what extent. In addition, it would be useful to conduct impervious drainage analysis on Round One data to allow for direct comparisons regarding increases in impervious cover since Round One and whether observed changes in biological condition can be correlated to such changes.

Biological communities respond to a combination of environmental factors, commonly referred to as stressors. Stressors can be organized according to the five major determinants of biological integrity in aquatic ecosystems, which include water chemistry, energy source, habitat structure, flow regime, and biotic interactions (Karr et al., 1986; Angermeier and Karr, 1994; Karr and Chu, 1998). The cumulative effects of human activities within the County's sampling units often results in an alteration of at least one, if not several, of these factors with detrimental consequences for the aquatic biota. Determining which specific stressors are responsible for the observed degradation within a stream or PSU is a challenging task, given that many stressors co-exist and synergistic effects can occur. Furthermore, an added challenge in identifying the stressors affecting stream biota is that the water

quality and physical habitat data collected by the County's monitoring program are not comprehensive (i.e., they do not include many possible stressors). For instance, virtually no data are available regarding biotic interactions and energy sources and only limited data regarding flow regime variables, such as land use and impervious cover, are included. Stressor relationships with stream biotic components, and their derived indices (i.e., BIBI), are often difficult to partition from complex temporal-spatial data sets primarily due to the potential array of multiple stressors working at the reach to landscape scale in small streams (Helms et al. 2005; Miltner et al., 2004; Morgan and Cushman, 2005; Volstad et al., 2003; Morgan et al., 2007). Therefore, it should be noted that the current level of analysis cannot identify all stressors for the impaired watersheds, nor will the stressors identified include all of the stressors present.

## **5.1 Recommendations for Future Program Development**

### Additional Water Quality Sampling

The 'Supporting' and 'Partially Supporting' habitat conditions identified were not always substantiated by a healthy benthic community. This can be an indication of degraded water quality conditions. Although very few of the water quality parameters measured (pH only) were outside of the acceptable COMAR standards, additional sampling is recommended, especially on those streams rated as 'Poor' or 'Very Poor' for biological condition, in order to determine whether there are other chemical stressors affecting the biota.

In 2016, conductivity levels were the only measured parameter considered high across many of the sites. However, the limited number of water quality parameters measured during the spring sampling season decreases the ability to identify specific stressors. A more in-depth analysis of water quality could be performed to determine the types and potential sources of pollutants. Supplementary sampling should evaluate additional parameters such as nutrients and metals, which may potentially be of concern.

Because the biological monitoring is conducted generally under baseflow conditions there is the potential for missing pollutants associated with stormwater runoff, specifically in more urbanized portions of the watershed. Wet weather monitoring in these watersheds could also be conducted to determine the presence of additional water quality stressors.

While water quality sampling would add considerable costs to the monitoring program, the added benefit would greatly enhance the County's ability to identify predominant water quality stressors and sources. Additionally the program would be positioned well to monitor changes in water chemistry as it relates to tracking progress towards meeting total maximum daily load (TMDL) requirements, both for specific impaired water bodies and for the Chesapeake Bay-wide TMDL.

### Comparability with Statewide Methods

Howard County adopted the DNR's MBSS methods in 2001. The MBSS program continues to evolve and refine their sampling design, field procedures, and data analysis protocols, with the most recent field sampling protocols having been updated in 2014. While no changes have occurred to the benthic macroinvertebrate collection methods implemented herein, additional surveys have been added to the data collection efforts (i.e., vernal pool search, invasive vegetation search), which may be of interest to the County. The County should continue to update their methods in the future to stay current with the latest MBSS sampling protocols, especially with regard to benthic macroinvertebrate sampling. In addition, the County should continue to ensure that all personnel collecting macroinvertebrate samples have been certified by MBSS in benthic macroinvertebrate sample collection procedures.

### Quality Assurance and Quality Control

The QA/QC procedures outlined in the Quality Assurance Project Plan (QAPP) for the Howard County Biological Monitoring and Assessment Program (Howard County, 2001) should be re-evaluated considering the evolution of the metric scoring system, which may not be appropriate for incremental data such as that found in the scaled BIBI metrics.

The BIBI scoring system is not continuous. That is, each metric is assigned a value of 1, 3, or 5 and then averaged for a final BIBI score. This means that scores increase incrementally by 0.3 or 0.4. Additionally, the relative percent difference (RPD) between low scores (2.0 and 2.3) will be higher than a comparison of higher scores (4.7 and 5.0). This can lead to a site not meeting the measurement quality objective (MQO) despite the scores being only one scoring increment apart. A relatively minor difference between samples can lead to the MQO not being met.

### Fish Community Assessments

MBSS conducts fish sampling during the summer index period, which provides additional information regarding stream biodiversity. Fish species exhibit diverse morphological, ecological, and behavioral adaptations to their natural habitat and, consequently, are particularly effective indicators of the condition of aquatic systems (Karr et al., 1986; Fausch et al., 1990; Simon and Lyons, 1995; McCormick et al., 2001). Given that fish assemblages respond differently to some stressors than benthic macroinvertebrate assemblages, data from fish sampling can assist in identifying stressors that may be impacting specific streams as well as provide an improved understanding of the biological condition of streams throughout the County via the combined index of biotic integrity (CIBI), which incorporates both BIBI and fish IBI (FIBI) results into a single biological index. Furthermore, fish sampling data can be used to evaluate biotic interactions, particularly the effects of non-native and invasive species on native fauna. It is recommended that the County consider the addition of fish sampling to their program to not only allow for a more comprehensive assessment of the biological condition of the County's streams, but also to assist in the identification of additional stressors impacting their streams. Furthermore, the addition of fish sampling will allow for improved data sharing between the County and State agencies (i.e., DNR, MDE), which is essential to the protection and preservation of the Chesapeake Bay.

### Geomorphic Assessments

While Rosgen Level II assessments provide useful information for characterizing the overall channel morphology, stream classification was not shown to be a useful predictor of biological condition or current land use characteristics in neighboring Anne Arundel County (Hill and Pieper, 2011; Hill et al., 2014). It is likely that the dominant geomorphological processes (i.e., erosion, transport, or deposition) are more important to the condition of the benthic macroinvertebrate communities than the current stream type as classified by the Rosgen approach. Perhaps a more rapid assessment of each reach using the channel evolution model (CEM; Schumm et al. 1984, Simon and Hupp 1986, and Simon 1989) would provide sufficient data regarding the geomorphological processes in each stream. The CEM identifies distinct stages of a channel's progression from a pre-modified condition through incising, widening, aggrading, re-stabilizing, and back to a quasi-equilibrium state, which may be observed in one reach overtime or various stages may be observed within an entire drainage network at a given time.

1 Drainage areas provided are delineated to each sampling site.  
 2 See text for discussion of impervious percent. Bold values derived from land use and land cover.  
 3 Land use is based on Maryland Department of Planning (MDP) 2010 data.  
 4 Numbers in parentheses correspond to MDP land use codes.

1 Life Stage, I - Immature, P- Pupa, A - Adult, U - Undetermined; 2 Functional Feeding Group; 3 Primary habit or form of locomotion, includes bu - burrower, cn - clinger, cb - climber, sk - skater, sp - sprawler, sw - swimmer; 4 Tolerance Values, based on Hilsenhoff, modified for Maryland. An entry of "0" indicates information for the particular taxa was not available.

1 Life Stage, I - Immature, P- Pupa, A - Adult, U - Undetermined; 2 Functional Feeding Group; 3 Primary habit or form of locomotion, includes bu - burrower, cn - clinger, cb - climber, sk - skater, sp - sprawler, sw - swimmer; 4 Tolerance Values, based on Hilsenhoff, modified for Maryland. An entry of "0" indicates information for the particular taxa was not available.

1 Life Stage, I - Immature, P- Pupa, A - Adult, U - Undetermined; 2 Functional Feeding Group; 3 Primary habit or form of locomotion, includes bu - burrower, cn - clinger, cb - climber, sk - skater, sp - sprawler, sw - swimmer; 4 Tolerance Values, based on Hilsenhoff, modified for Maryland. An entry of "0" indicates information for the particular taxa was not available.

1 Life Stage, I - Immature, P - Pupa, A - Adult, U - Undetermined; 2 Functional Feeding Group; 3 Primary habit or form of locomotion, includes bu - burrower, cn - clinger, cb - climber, sk - skater, sp - sprawler, sw - swimmer; 4 Tolerance Values, based on Hilsenhoff, modified for Maryland. An entry of "0" indicates information for the particular taxa was not available.

1 Life Stage, I - Immature, P- Pupa, A - Adult, U - Undetermined; 2 Functional Feeding Group; 3 Primary habit or form of locomotion, includes bu - burrower, cn - clinger, cb - climber, sk - skater, sp - sprawler, sw - swimmer; 4 Tolerance Values, based on Hilsenhoff, modified for Maryland. An entry of "0" indicates information for the particular taxa was not available.

1 Life Stage, I - Immature, P- Pupa, A - Adult, U - Undetermined; 2 Functional Feeding Group; 3 Primary habit or form of locomotion, includes bu - burrower, cn - clinger, cb - climber, sk - skater, sp - sprawler, sw - swimmer; 4 Tolerance Values, based on Hilsenhoff, modified for Maryland. An entry of "0" indicates information for the particular taxa was not available.

<sup>1</sup> Life Stage, I - Immature, P- Pupa, A - Adult, U - Undetermined; <sup>2</sup> Functional Feeding Group; <sup>3</sup> Primary habit or form of locomotion, includes bu - burrower, cn - clinger, cb - climber, sk - skater, sp - sprawler, sw - swimmer; <sup>4</sup> Tolerance Values, based on Hilsenhoff, modified for Maryland. An entry of "0" indicates information for the particular taxa was not available.

**Appendix D: Habitat Assessment Data**

**Appendix F: Quality Assurance/Quality Control**

---

The biological monitoring program for the Rocky Gorge, Hammond Branch, and Dorsey Run subwatersheds includes chemical, physical, and biological assessments conducted throughout the selected PSUs. The sampling methods used are compatible with the Design of the Biological Monitoring and Assessment Program for Howard County Maryland (Tetra Tech, 2001) and the Quality Assurance Project Plan (QAPP) for Howard County Department of Public Works (Tetra Tech, 2001). A summary of the Quality Assurance/Quality Control (QA/QC) procedures and results are presented in this Appendix.

A quality assurance and quality control analysis was completed for the assessment work conducted in the Rocky Gorge, Hammond Branch, and Dorsey Run subwatersheds following the methods described by Hill et al. (2005). This analysis included performance characteristics of precision, accuracy, bias and completeness. Performance measures include:

- Precision (consistency) of field sampling and overall site assessments using intra-team site duplication
  - median relative percent difference (mRPD)
  - coefficient of variability (CV)
  - 90% confidence interval (CI)
- Bias of sample sorting and subsampling
  - percent sorting efficiency (PSE)
- Accuracy of data entry
  - number of errors/corrective actions
- Completeness
  - number of valid data points obtained as a proportion of those planned (QAPP, 2001).

Data that does not meet performance or acceptable criteria are re-evaluated to correct any problems or investigated further to determine the cause of any discrepancies.

### **Field Sampling**

All field crew members collecting biological samples were recently trained in MBSS Spring Sampling protocols and certified in benthic macroinvertebrate sample collection procedures by MBSS. All subjective scoring was completed with the input of all team members at the sampling site to reduce individual sampler bias.

Field water quality measurements were collected *in situ* at all monitoring sites including the duplicate sites, according to methods in the County QAPP. All *in situ* parameters were measured with a YSI Pro Plus series multiprobe, except turbidity which was measured using a Hach 2100 Turbidimeter. Water quality equipment was regularly inspected, maintained and calibrated to ensure proper usage and accuracy of the readings. Calibration logs were kept by field crew leaders and checked by the project manager regularly.

Sample buckets contained both internal and external labels. All chain-of-custody procedures were followed for transfer of the samples between the field and the identification lab.

Replicate (duplicate) samples were collected at ten percent of the sites (one site for each PSU, three total for the 2016 sampling year). These QC samples were collected to determine the consistency and precision of the sampling procedures and the intra-team adherence to those protocols. QC sites were field-selected rather than randomly selected to ensure that the QC sites maintained similar habitat conditions to the original site. Data collected from duplicate sites included water quality, benthic macroinvertebrate samples, and completion of the RBP habitat assessment. Photographs were also taken at duplicate sites.

*Precision*

Measures of precision calculated for the consistency of field sampling using intra-team site duplication were:

- Median relative percent difference (mRPD) and relative percent difference (RPD)
- Coefficient of variability (CV)
- 90% confidence interval (CI)

Acceptable measurement quality objectives (MQO) are listed in the table below. DNR’s MBSS protocols were used for the collection and analysis of macroinvertebrate data. In 2005, DNR updated their Benthic Index of Biotic Integrity (BIBI; Southerland et al., 2005). These new metrics were used to calculate the BIBI presented in this report.

**Measurement Quality Objectives (QAPP, 2001)**

| Metric or Index                 | Precision | Accuracy      | Completeness (%) |
|---------------------------------|-----------|---------------|------------------|
| GPS                             |           | ± 25m         | 100              |
| Dissolved Oxygen                | RPD ≤ 20% | ± 0.2 mg/L    | ≥ 85             |
| pH                              | RPD ≤ 20% | ± 0.2 units   | ≥ 85             |
| Temperature                     | RPD ≤ 20% | ± 0.15 °C     | ≥ 85             |
| Conductivity                    | RPD ≤ 20% | ± 1% of value | ≥ 85             |
| RBP Physical Habitat Assessment | RPD ≤ 20% | NA            | 100              |
| Macroinvertebrate taxa          |           |               | 100              |
| Metric Scores                   | RPD ≤ 5%  |               |                  |
| Bioassessment Scores            | RPD ≤ 5%  |               |                  |
| Sorting Efficiency              | SE ≥ 90%  |               |                  |

**GPS**

All GPS points were collected with a Trimble ProXT GPS unit capable of accuracy of within 2 meters. Multiple readings (approximately 60) were recorded at the reach midpoint and averaged to obtain the location of the final point. Thus, the accuracy requirement of ± 25 meters was met. A GPS point was collected at all 30 sites, therefore the data meets the 100 percent MQO for completeness.

**Water Quality**

The following table shows the results of the water quality MQO analysis. The field equipment used, with correct maintenance and calibration, are capable of the required accuracy. Since the true accuracy of field measured water quality is not known with confidence, the measure of precision is used instead. Water quality data for all parameters were collected at all 30 sites, therefore the data meets the >85 percent MQO for completeness. One sample pair (09RG-102-R-2016A) had a water quality measurement that exceeded the MQO of ≤20% for turbidity. The calculated RPD for this sample pair was 64.15, above the stated MQO. However, the high RPD value is an artifact of comparing two low values. This automatically results in an inflated RPD value despite a difference of 1.02 NTU between the samples. All other water quality parameters were within the acceptable ranges for precision.

**Measurement Quality Objectives Results – Water Quality. Bold records indicate values exceeding stated MQOs.**

|                     | Dissolved Oxygen (mg/l) | pH   | Water Temperature (°C) | Turbidity (ntu) | Conductivity (µS/cm) |
|---------------------|-------------------------|------|------------------------|-----------------|----------------------|
| 09RG-102-R-2016A    | 10.76                   | 7.09 | 12.70                  | 1.1             | 280.4                |

| Median RPD          | 2.48                    | 3.19 | 2.61                   | 8.89            | 1.80                 |

**Habitat Assessment**

The following table provides the result of the MQO analysis for the habitat assessment. The RPD was <10 percent for all QC sites, therefore, all data meets the MQO of ≤20 percent.

**Measurement Quality Objectives Results – Habitat Assessment (RBP)**

|                     | RBP Total Score | RBP Percent Comparability | Narrative Rating     |
|---------------------|-----------------|---------------------------|----------------------|
| 14HB-123-F-2016I    | 156             | 78                        | Supporting           |
| 14HB-123-F-2016I QC | 153             | 77                        | Supporting           |
| Absolute Difference | 3.00            | 1.50                      |                      |

| Median RPD          | 1.94            | 1.94                      |                      |

**Biological Assessment**

The following three tables include the results of the QC analysis for the biological metrics and BIBI scores. A few metric scores fell outside the acceptable range for precision (shown in bold). In each case, the difference was only one scoring class (i.e, 1, 3, or 5), which resulted in a large RPD. In fact, even the smallest incremental difference in metric scores would result in an exceedance of the RPD MQO. Therefore, additional measures of precision were calculated among the combined QC data set to evaluate the significance of the differences in individual metric values and scores, as well as in the overall BIBI score.

**Measurement Quality Objectives Results – Biological Sampling, Sample Pair RPD for Metric and IBI Scores**

|                    | BIBI        | Total Taxa Score | EPT Taxa Score | Ephem Taxa Score | Percent Intolerant Urban Score | Percent Chironomidae Score | Percent Clinger Score |
|--------------------|-------------|------------------|----------------|------------------|--------------------------------|----------------------------|-----------------------|
| 09RG-102-R-2016A   | 4.67        | 5                | 5              | 3                | 5                              | 5                          | 5                     |
| 09RG-102-R-2016AQC | 3.67        | 3                | 3              | 3                | 5                              | 3                          | 5                     |
| 14HB-123-F-2016I   | 2.67        | 5                | 1              | 3                | 3                              | 3                          | 1                     |
| 14HB-123-F-2016IQC | 2.00        | 5                | 3              | 1                | 1                              | 1                          | 1                     |
| 15DR-119-F-2016G   | 1.33        | 3                | 1              | 1                | 1                              | 1                          | 1                     |
| 15DR-119-2016GQC   | 1.33        | 3                | 1              | 1                | 1                              | 1                          | 1                     |
| <b>Median RPD</b>  | <b>24.0</b> | 0.0              | <b>50.0</b>    | 0.0              | 0.0                            | <b>50.0</b>                | 0.0                   |

The BIBI is not scored on a continuous scale, but rather each metric is scored on an incremental scale (assigned a value of 1, 3 or 5), and these values are averaged to yield the final BIBI score. Since the piedmont BIBI score is an average of six metric scores, the BIBI scores shift by at least 0.3 or 0.4 with a difference in only metric (e.g., 2.0, 2.3, 2.7, 3.0). Additionally, an individual metric value may differ by only one taxa or one percent for a sample pair, but if it falls on either side of a scoring threshold (i.e, 1, 3, 5), the resulting difference in metric scores will differ by as much as 50 to 100% for RPD. For these reasons, the EPT Taxa score and Percent Chironomidae score mRPDs did not meet the MQOs.

Due to the overall BIBI score consisting of scaled incremental metrics, the RPD does not reflect the precision well. Additional measures of precision (CV, CI, and mRPD) for the combined sample pair results indicate far better precision than does RPD. None of the measures calculated deviated significantly from normal, acceptable levels of precision between duplicate sample pairs observed in similar studies (Hill et. al, 2005; Gallardo et. al, 2006).

All phases of the biological assessment were conducted for every site; therefore the 100 percent completeness MQO is met.

**Laboratory Sorting and Subsampling**

Only one highly qualified sorter was used to sort the 30 countywide samples. After 10 samples were sorted, the laboratory QC officer randomly selected one sample to resort to check the sorting efficiency of the technician. The target sorting efficiency rate for this project was 90%. The sorting technician saved the sample debris that was originally sorted for each sample and stored it in a separate container for QC purposes. The QC officer resorted the sample portion that was originally sorted and removed, counted, and added any organisms originally missed to the sample vials for identification.

Two samples were checked by the QC officer for this project, and both samples passed the QC with an error rate of 0.0% and 3.4%. Collectively the samples had an average sorting efficiency of 98.3%, which exceeds the sorting efficiency target of 90%.

### **Taxonomic Identification and Enumeration**

Two samples (RG09-413-R-2016E and 15DR-121-F-2016H) were randomly selected for QC identification and enumeration by an independent lab. Original identification was completed by Aquatic Resources Center<sup>1</sup>. Re-identification of the randomly selected sample was done by Ellen Friedman of Maryland Department of Natural Resources. Each sample was identified to the genus level where possible. Individuals that were not able to be identified to genus level were identified to the lowest possible level, usually family, but in some cases order or subphylum. For Chironomidae, individuals not identifiable to genus may have been identified to subfamily or tribe level.

#### *Precision*

Measures of precision were calculated for the identification consistency between the two randomly selected samples. These include percent difference in enumeration (PDE) and percent taxonomic disagreement (PTD).

The PDE compares the final specimen counts between the two taxonomy labs, whereas PTD compares the number of agreements in final specimen identifications between the two taxonomic labs. While MBSS does not specify MQOs for these measures, performance characteristics were compared to recommended standards from Stribling et al. (2003), whereby the PDE for each sample should be equal to or less than 5%, and the PTD should be equal to or less than 15%. Results for the taxonomic comparison and resulting values for PDE and PTD are found in Table 1 and Table 2 for samples RG09-413-R-2016E and 15DR-121-F-2016H, respectively.

Both PDE (0.00% and 0.47%) and PTD (6.60 and 1.89%) were well below the threshold values for acceptance of 5% and 15%, respectively, indicating good overall taxonomic agreement. Minor hierarchical differences for chironomids were observed between the labs. All other disagreements were minor.
